The rapidly expanding body of available genomic and protein structural data provides a rich resource for understanding protein dynamics with biomolecular simulation. While computational infrastructure has grown rapidly, simulations on an omics scale are not yet widespread, primarily because software infrastructure to enable simulations at this scale have not kept pace. It should now be possible to study protein dynamics across entire (super)families, exploiting both available structural biology data and conformational similarities across homologous proteins. Here, we present a new tool for enabling high-throughput simulation in the genomics era. Ensembler takes any set of sequences—from a single sequence to an entire superfamily and shepherds them through various stages of modeling and refinement to produce simulation-ready structures. This includes comparative modeling to all relevant PDB structures (which may span multiple conformational states of interest), reconstruction of missing loops, addition of missing atoms, culling of nearly identical structures, assignment of appropriate protonation states, solvation in explicit solvent, and refinement and filtering with molecular simulation to ensure stable simulation. The output of this pipeline is an ensemble of structures ready for subsequent molecular simulations using computer clusters, supercomputers, or distributed computing projects like Folding@home. Ensembler thus automates much of the timeconsuming process of preparing protein models suitable for simulation, while allowing scalability up to entire superfamilies. [JDC: Prior sentence is redundant?] A particular advantage of this approach can be found in the construction of kinetic models of conformational dynamics—such as Markov state models—which benefit from a diverse array of initial configurations that span the accessible conformational states to aid sampling. We demonstrate the power of this approach by constructing models for all catalytic domains in the human tyrosine kinase family, using all available kinase catalytic domain structures from any organism as structural templates.

Ensembler is free and open source software licensed under the GNU General Public License (GPL) v2. It should run on all major operating systems, and has been tested on Linux and OS X. The latest release can be installed via the conda package manager, and the latest source can be downloaded from https://github. com/choderalab/ensembler.

Keywords: molecular dynamics simulation; comparative modeling; distributed simulation

I. INTRODUCTION

Recent advances in genomics and structural biology have 8 helped generate an enormous wealth of protein data at 9 the level of amino-acid sequence and three-dimensional 10 structure. However, proteins typically exist as an ensemble of thermally accessible conformational states, and static structures provide only a snapshot of their rich dynamical behavior. Many functional properties—such as the ability to bind small molecules or interact with signaling partners-require transitions between states, encompassing anything from reorganization of sidechains at binding interfaces to domain motions to large scale folding-unfolding events. Drug discovery could also benefit from a more extensive consideration of protein dynamics, whereby small molecules might be selected based on their predicted ability to bind and trap a protein target in an inactive state [? 22

Molecular dynamics (MD) simulations have the capability, 24 in principle, to describe the time evolution of a protein in atomistic detail, and have proven themselves to be a useful tool in the study of protein dynamics. A number of ma-

27 ture software packages and forcefields are available, and

₂₈ much recent progress has been driven by advances in com-29 puting architecture. For example, many MD packages are 30 now able to exploit GPUs, which provide greatly improved 31 simulation efficiency per unit cost relative to CPUs, while 32 distributed computing platforms such as Folding@home [CITE], GPUGrid [CITE], and Copernicus [CITE] allow scala-34 bility on an unprecedented level. In parallel, methods for 35 building human-understandable models of protein dynam-36 ics from noisy simulation data, such as Markov state mod-37 eling (MSM) approaches, are now reaching maturity [CITE 38 MSM reviews]. MSM methods in particular have the advan-39 tage of being able to aggregate data from multiple indepen-40 dent MD trajectories, facilitating parallelization of produc-41 tion simulations and thus greatly alleviating overall compu-42 tational cost. There also exist a number of mature software ₄₃ packages for comparative modeling of protein structures, in 44 which a target protein sequence is modeled using one or 45 more structures as templates [CITE Modeller and Rosetta and a recent homology modeling review].

However, it remains difficult for researchers to exploit the 48 full variety of available protein sequence and structural data 49 in simulation studies, largely due to limitations in software 50 architecture. For example, the set up of a biomolecular sim-51 ulation is typically performed manually, encompassing a se-52 ries of fairly standard (yet time-consuming) steps such as 53 the choice of protein sequence construct and starting struc-

^{*} Corresponding author; john.chodera@choderalab.org

54 ture, addition of missing residues and atoms, solvation with 109 explicit water and salt buffer, choice of simulation parameters, and system relaxation with energy minimization and one or more short MD simulations. For this reason, simulation studies typically consider only one or a few proteins and starting configurations.

The ability to fully exploit the large base of available protein sequence and structural data in biomolecular simulation studies could open up many interesting avenues for research, enabling the study of entire protein families or superfamilies across multiple organisms. The similarity between members of a given protein family could be exploited to generate arrays of conformational models, which could be used as starting configurations to aid sampling in MD simulations. This approach would be highly beneficial for many MD methods, such as MSM construction, which require global coverage of the conformational landscape to realize their full potential, and would also be particularly useful in cases where structural data is present for only subset of the members of a protein family. It would also aid in studying protein families known to have multiple metastable conformations—such as kinases—for which the combined body of structural data for the family may cover a large range of these conformations, while the available structures for any individual member might encom-₇₉ pass only one or two distinct conformations.

Here, we present the first steps toward bridging the 134 gap between biomolecular simulation software and omicsscale sequence and structural data: a fully automated open 136 This results in a total of almost 400,000 models, and we 148 'domain: "Protein kinase" AND taxonomy: 9606 AND the tool will prove to be useful in a number of other ways. 154 identifier for each target protein. II. DESIGN AND IMPLEMENTATION

Ensembler is written in Python, and can be used via a command-line tool (ensembler) or via a flexible Python API.

The **Ensembler** modeling pipeline comprises a series of 113 stages which are performed in a defined order. A visual overview of the pipeline is shown in Fig. 1. The various stages of this pipeline are described in detail below.

[JDC: We could really help the reader if we preface each 117 section here with a bit of an introduction of what we're trying to accomplish in each stage. Otherwise, I worry that 119 each section is a long list of things we do without reference to an overall concept of what the stage is trying to ac-121 complish or why certain decisions were made.] [DLP: Good point. I've added in brief introductions for each section.] 123 [JDC: Can you do a bit more here? I feel that the reader may need more orientation. You've essentially just added a sentence or two at the beginning of each stage that doesn't re-126 ally enlighten the user as to your terminology (tempalte and target), your motivation for why things are done each stage, or how the user is to select among the various options avail-129 able.]

Target selection

The first stage entails the selection of a set of target protein sequences, i.e. the sequences the user is interested in modeling. [JDC: Maybe explain what is meant by "target protein sequences"? These are the sequences the user is interested in modeling.] [DLP: Addressed.]

These targets can be defined manually, simply by prosource framework for building simulation-ready protein 137 viding a FASTA-formatted text file containing the desired models in multiple conformational substates scalable from 138 target sequences with arbitrary identifiers. The ensembler single sequences to entire superfamilies. Ensembler pro- 139 command-line tool also allows targets to be selected vides functions for selecting target sequences and homolo- 140 from UniProt—a freely accessible resource for protein gous template structures, and (by interfacing with a num- 141 sequence and functional data (uniprot.org) [JDC: Isn't ber of external packages) performs pairwise alignments, 142 there a real citation for UniProt?], using the subcommand comparative modeling of target-template pairs, and several [143] gather_targets. The user specifies a query string with stages of model refinement. As an example application, we 144 the --query flag, which conforms to the same syntax have constructed models for the entire set of human tyro- 145 as the search function available on the UniProt website. sine kinase catalytic domains, using all available structures 146 For example, --query 'mnemonic: SRC_HUMAN' would of protein kinase domains (from any species) as templates. ¹⁴⁷ select the full-length human Src sequence, while --query demonstrate that these provide wide-ranging coverage of 149 reviewed: yes' would select all human protein kinases known functionally relevant conformations. By using these 150 which have been reviewed by a human curator. In this models as starting configurations for highly parallel MD sim- us way, the user may select a single protein, many proteins, ulations, we expect their structural diversity to greatly aid 152 or an entire superfamily. The program outputs a FASTA in sampling of conformational space. We anticipate that 153 file, setting the UniProt mnemonic (e.g. SRC_HUMAN) as the

Matching residues then extracted from the original coordinate files and stored as 275 the goal is to provide good coverage of conformation space, PDB-format coordinate files.

fashion as for target selection; the --query flag is used to $_{278}$ Python library is used to calculate RMSD (for $C\alpha$ atoms only) select full-length proteins from UniProt, while the optional 279 with a fast quaternion characteristic polynomial (QCP) [Cite each protein includes a list of associated PDB chains and 282 tance cutoff (which defaults to 0.6 Å) is used to retain only a their residue spans, and this information is used to select 283 single model per cluster. template structures, using the same method as for template selection from the PDB. Only structures solved by X-ray crystallography or NMR are selected, thus excluding computergenerated models available from the PDB. If the --domains flag is used, then templates are truncated at the start and end of the domain sequence.

Unresolved template residues can optionally be remodeled with the loopmodel subcommand, which employs kinematic closure algorithm [CITE] provided via the loopmodel tool of the Rosetta software suite (CITE: Rosetta and/or loopmodel). Because fewer loops need to be built during the subsequent model-building stage, prebuilding template loops tends to provide higher-quality models after completion of the **Ensembler** pipeline. Loop remodeling may fail for a small proportion of templates due to spatial constraints imposed by the original structure; the subsequent modeling step thus automatically uses the remodeled version of a template if available, but otherwise falls back to using the non-remodeled version. Furthermore, the Rosetta loopmodel program will not model missing residues at the termini of a structure—such residues spans are modeled in the subsequent stage.

Modeling

251

This stage entails the generation of models via comparative modeling of each target sequence onto each template 308 structure. Non-unique models are subsequently filtered out 309 sing a RMSD-based clustering scheme.

tion [CITE: Modeller], which implements comparative struc- 312 ter and performing a round of explicit-solvent MD refineture modeling by satisfaction of spatial restraints [CITE: Sali 313 ment/equilibration under isothermal-isobaric (NPT) condi-Blundell J Mol Biol 1993; Fiser Sali Prot Sci 9 2000]. While 314 tions. The solvation step solvates each model for a given Modeller can generate alignments automatically, we uti- 315 target with the same number of waters to facilitate the intelize the BioPython pairwise2 module [CITE: BioPython]— 316 gration of data from multiple simulations, such as the con-

Acids Res 2013), which provides residue-level mappings be- 264 Gonnet Science 1992], which we have empirically found tween PDB and UniProt entries. The SIFTS data is used to ex- 265 to produce better quality alignments for purposes of hightract template sequences, retaining only residues which are 266 throughput model building. Models are output as PDBresolved and match the equivalent residue in the UniProt $_{267}$ format coordinate files. A list of all model identifiers sorted sequence—non-wildtype residues are thus removed from 268 by sequence identity is also written to a text file. To minithe template structures. Furthermore, PDB chains with less 269 mize file storage requirements, **Ensembler** uses the Python than a given percentage of resolved residues (default: 70%) 270 gzip library to apply compression to all sizeable text files

All chains of template structures that contain the tem-₂₇₃ plate sequence are utilized in the modeling phase, which 274 can sometimes cause models to be nearly identical. Since 276 Ensembler filters out nearly identical models using struc-Selection of templates from UniProt proceeds in a similar 277 tural similarity-based clustering. The mdtraj [CITE: mdtraj] - -domains flag allows selection of individual domains with $_{\scriptscriptstyle 280}$ Theobald QCP papers] implementation, and the leader alregular expression string. The returned UniProt data for 281 gorithm is then used to populate clusters. A minimum dis-

Refinement

This stage entails the use of molecular dynamics simula-286 tions to refine the models built in the previous step. This helps to improve model quality and also prepares models for subsequent production simulation, including solvation with explicit water molecules, if desired.

Models are first subjected to energy minimization (using the L-BFGS algorithm [CITE]), followed by a short molecular 292 dynamics (MD) simulation with an implicit solvent represen-293 tation. This is implemented using the OpenMM molecular 294 simulation toolkit (link and CITE: OpenMM), chosen for its ₂₉₅ flexible Python API, and high performance GPU-acclerated simulation code. By default, the Amber99SB-ILDN force field is used [CITE: amber99sbildn refs] with a modified generalized Born solvent model (GBSA-OBC) (CITE: GBSA-OBC). The **Ensembler** API allows the use of any of the other force fields implemented in OpenMM. The simulation is run for a default of 100 ps to filter out poor quality models (where atomic overlaps that cannot be resolved by energy minimization would cause the simulation to explode) and help relax models for subsequent production simulation. [JDC: What criteria were applied to filter out poor models? Do we only look for thrown exceptions or NaNs? Or do we use an energy filtering criteria too?] [DLP: We currently just filter out models which throw exceptions or NaNs.]

While protein-only models may be sufficient for struc-310 tural analysis or implicit solvent simulations, Ensembler Modeling is performed with the Modeller automodel func- 👊 also provides a stage for solvating models with explicit wawhich uses a dynamic programming algorithm—with the 317 struction of MSMs. The target number of waters is selected

318 by first solvating each model with a specified padding dis- 366 tance (default: 10 Å), then taking a percentile value from the distribution (default: 68th percentile). [JDC: Would be useful to explain why we are doing this.] [DLP: Addressed.] This helps to prevent models with particularly long, extended loops—such as those arising from template structures with unresolved termini—from imposing very large box sizes on the entire set of models. Models are resolvated with the target number of waters by first solvating with zero padding, then incrementally increasing the box size and resolvating until the target is exceeded, then finally deleting sufficient waters to match the target value. The explicit solvent MD simulation is also implemented using OpenMM, using the Amber99SB-ILDN force field and TIP3P water [JDC: CITE] by default. Other force fields or water models such as TIP4P-Ew [CITE]) can be specified via the **Ensembler** API. [JDC: We should allow other water models in OpenMM too, such as TIP4P-Ew?] [DLP: I forgot to mention this in the text previously - any of the OpenMM force fields can be chosen via the 337 API. I've updated the text accordingly. Is this functionality 338 sufficient? I guess it's ok to leave ff choice as an "advanced" feature which requires use of the API? Otherwise I could add --water_model flag to the CLI, for example.]

Packaging

341

347

354

Ensembler provides a packaging module which can be 389 used to compress models in preparation for data transfer, or to prepare models with the appropriate directory and file structure for subsequent production simulations on the dis-346 tributed computing platform Folding@home (CITE: F@H).

Provenance

To aid the user in tracking the provenance of each model, 348 each pipeline function also outputs a metadata file, which helps to link data to the software version used to generate it (both **Ensembler** and its dependencies), and also provides timing and performance information, and other data such as hostname.

Rapidly modeling a single template

365 number of models generated.

RESULTS

[JDC: It would be useful to have some subheadings in this 368 section to give it some internal organization.]

Modeling of all human tyrosine kinase catalytic domains

As a first application of **Ensembler**, we have built mod-371 els for all 90 human tyrosine kinase (TK) domains listed 372 in UniProt. [JDC: Is there a complete list of these some-373 where? Maybe reference supplementary data?] TKs (and protein kinases in general) play important roles in many cel-375 lular processes and are involved in a number of types of 376 cancer. [JDC: CITE] For example, mutations of Src are as-377 sociated with colon, breast, and prostate cancer [CITE: Src cancer involvement], while a translocation between the TK 379 Abl1 and the pseudokinase Bcr is closely associated with 380 chronic myelogenous leukemia [CITE: Abl1 cancer involvement]. Protein kinase domains are thought to have multiple accessible metastable conformation states, with a single ac-383 tive conformation, and much effort is directed at developing 384 kinase inhibitor drugs which bind to and stabilize inactive conformations [CITE: Lee and Craik Science 2009]. [JDC: Lee and Craik do not discuss kinases, I don't believe; you'll have to find an accurate reference on kinase conformations.] Ki-388 nases are thus a particularly interesting subject for study with MSM methods [CITE: recent kinase MSM papers], and this approach stands to benefit greatly from the ability to exploit the full body of available genomic and structural data within the kinase family, e.g. by generating large numbers of 393 starting configurations to be used in highly parallel MD sim-394 ulation.

We selected all available structures of protein kinase domains (of any species) as templates, for a total of 4433 (398,970 target-template pairs). The templates were derived from 3028 individual PDB entries and encompassed 23 different species, with 3634 template structures from human kinase constructs.

Ensembler modeling statistics

Unresolved template residues were first remodeled us-403 ing the loopmodel subcommand. The number of miss-404 ing residues in each template ranged from 0 to 102, with a 405 median of 11 and a standard deviation of 13. Out of 3666 For users interested in simply using **Ensembler** to rapidly 406 templates with one or more missing residues, 3134 were generate a set of models for a single template sequence, **En-** 407 successfully remodeled, with most remodeling failures atsembler provides a command-line tool quickmode1, which 408 tributable to spatial constraints imposed by the original performs the entire pipeline for a single target with a small $_{
m 409}$ template structure. There was some correlation between reumber of templates. For larger numbers of models (such as 410 modeling failures and the number of missing residues; tementire protein families), modeling time is greatly reduced by applates for which remodeling failed had a median of 20 missusing the main modeling pipeline, which is parallelized via 412 ing residues, compared to a median of 14 missing residues MPI, distributing computation across each model (or across 413 for templates for which remodeling was successful. The diseach template, in the case of the loop reconstruction code), 414 tributions are plotted in Fig. S1. [JDC: Can you give some and scaling (in a "pleasantly parallel" manner) up to the 415 statistics on the distribution of loop lengths modeled? Why 416 did loop modeling fail in the cases it did? Anything else you

417 can say here beyond this one sentence? [DLP: Addressed in 472 based on the sequence identity between the target and temthe text, and a SI figure.]

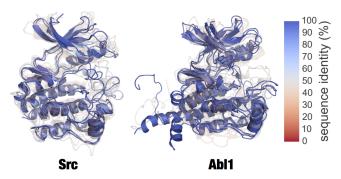

FIG. 4. Superposition of clustered models of Src and Abl1. Superposed renderings of nine models each for Src and Abl1, [JDC: Src and Abl, or Src and Abl1? The description should match the captions above.] [DLP: Addressed. Using Abl1, as this is the HGNC recommended symbol.] giving some indication the diversity of conformations generated by Ensembler. The models for each target were divided into three sequence identity ranges (as in Fig. 3), and RMSD-based k-medoids clustering was performed to select three clusters from each. The models shown are the centroids of each cluster. Models are colored and given transparency based on their sequence identity, so that high sequence identity models are blue and opaque, while lower sequence identity models are transparent and red.

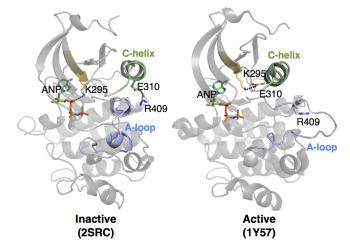

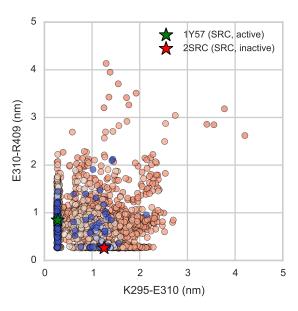

FIG. 5. Two structures of Src, indicating certain residues involved in activation. In the inactive state, E310 forms a salt bridge with R409. During activation, the α C-helix (green) moves and rotates, orienting E310 towards the ATP-binding site and allowing it to instead form a salt bridge with K295. This positions K295 in the appropriate position for catalysis.

₅₃₃ available through the conda package manager, and thus must be installed separately by the user. The latest source 535 can be downloaded from the above GitHub repository, 536 which also contains instructions for building and installing 537 the code.

Future Directions

[JDC: In the Discussion, let's be sure to talk about the lim-

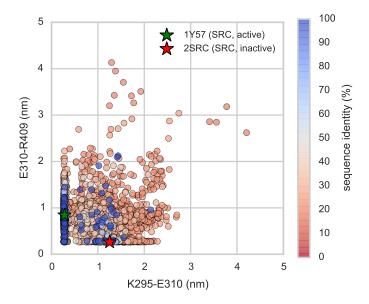

FIG. 6. Src and Abl1 models projected onto the distances between two conserved residue pairs, colored by sequence identity. Two Src structures (PDB entries 1Y57 [CITE] and 2SRC [CITE]) are projected onto the plots for reference, representing active and inactive states respectively. These structures and the residue pairs analyzed here are depicted in Fig. 5. Distances are measured between the center of masses of the three terminal sidechain heavy atoms of each residue. The atom names for these atoms, according to the PDB coordinate files for both reference structures, are—Lys: NZ, CD, CE (ethylamine); Glu: OE1, CD, OE2 (carboxylate); Arg: NH1, CZ, NH2 (part of guanidine).

541 ture. For example, we don't yet handle counterions (e.g. 572 tions combined with Monte Carlo sampling of side chain structural Zn²⁺), prosthetic groups (e.g. heme), or cofactors ₅₇₃ conformers to calculate pKa values. (e.g. ATP) vet. We don't handle post-translational modifications either (such as phosphorylation, methylation, glycosyation, etc.). It's a good idea to suggest that this is an important first step toward enabling superfamily- and genomicscale modeling, but there's a lot of work yet to be done.]

Comparative protein modeling and MD simulation set-up can be approached in a number of different ways, with varying degrees of complexity, and there are a number of obvious additions and improvements which we plan to implement in future versions of Ensembler.

553

Many proteins require the presence of various types of non-protein atoms and molecules for proper function, such $_{576}$ as metal ions (e.g. Mg^{+2}), cofactors (e.g. ATP) or post-577 translational modifications (e.g. phosphorylation, methyla-578 tion, glycosylation, etc.), and we thus plan for **Ensembler** to eventually have the capability to include such entities in the generated models. Binding sites for metal ions are frequently found in proteins, often playing a role in catalysis. For example, protein kinase domains contain two binding sites for divalent metal cations, and display significantly Some amino acids can exist in different protonation 584 increased activity in the presence of Mg²⁺ [CITE: Adams states, depending on pH and on their local environment. 585 Taylor Protein Sci 1993], the divalent cation with highest These protonation states can have important effects on bi- 586 concentration in mammalian cells. Metal ions are often ological processes. For example, long timescale MD simu- 587 not resolved in experimental structures of proteins, but by lations have suggested that the conformation of the DFG 588 taking into account the full range of available structural motif of the TK Abl1—believed to be an important regula- 589 data, it should be possible in many cases to include metal tory mechanism[CITE: Abl1 DFG flip evidence]—is controlled 590 ions based on the structures of homologous proteins. We by protonation of the aspartate [CITE: Shan Shaw Proton- 591 are careful to point out, however, that metal ion paramedependent switch Abl1 PNAS 2009]. Currently, protonation 592 ters in classical MD force fields have significant limitations, states are assigned simply based on pH (a user-controllable 593 particularly in their interactions with proteins [CITE: Sousa parameter). At neutral pH, histidines have two protonation 594 Ramos chapter 11 of Kinetics and Dynamics: From Nano- to states which are approximately equally likely, and in this sit- 595 Bio-Scale, Springer, 2010]. Cofactors and post-translational uation the selection is therefore made based on which state 596 modifications are also often not fully resolved in experiresults in a better hydrogen bond. It would be highly de- 597 mental structures, and endogenous cofactors are frequently sirable to instead use a method which assigns amino acid 598 substituted with other molecules to facilitate experimental protonation states based on a rigorous assessment of the 599 structural analysis. Again, Ensembler could exploit struclocal environment. We thus plan to implement an inter- 600 tural data from a set of homologous proteins to model in 570 face and command-line function for assigning protonation 601 these molecules, although there will be likely be a number 571 states with MCCE2 [?], which uses electrostatics calcula- 602 of challenges to overcome in the design and implementa603 tion of such functionality.

617

the set of all human protein kinase domains listed in UniProt 626 community. have a median length of 265 residues and a standard deviation of 45, yet the minimum and maximum lengths are 102 and 801 respectively. The latter value corresponds to 627 the protein kinase domain of serine/threonine-kinase great-₆₁₂ wall, which includes a long insertion between the two main ₆₂₈ could be excluded from the generated models, though a number of questions would arise as to how best to approach 616 this.

Conclusion

621 that it could likely prove useful for tasks beyond its original 640 Louis V. Gerstner Young Investigator Award.

₆₂₂ aim of providing diverse starting configurations for MD sim-Another limitation with the present version of Ensembler 623 ulations. The code is open source and has been developed involves the treatment of members of a protein family with 624 with extensibility in mind, in order to facilitate its customizaespecially long residue insertions or deletions.
