# Ensembler: Enabling high-throughput molecular simulations at the superfamily scale

Daniel L. Parton,<sup>1</sup> Patrick B. Grinaway,<sup>1</sup> Sonya M. Hanson,<sup>1</sup> Kyle A. Beauchamp,<sup>1</sup> and John D. Chodera<sup>1,\*</sup>

<sup>1</sup>Computational Biology Program, Sloan Kettering Institute, Memorial Sloan Kettering Cancer Center, New York, NY 10065 (Dated: June 25, 2015)

The rapidly expanding body of available genomic and protein structural data provides a rich resource for understanding protein dynamics with biomolecular simulation. While computational infrastructure has grown rapidly, simulations on an omics scale are not yet widespread, primarily because software infrastructure to enable simulations at this scale has not kept pace. It should now be possible to study protein dynamics across entire (super)families, exploiting both available structural biology data and conformational similarities across homologous proteins. Here, we present a new tool for enabling high-throughput simulation in the genomics era. Ensembler takes any set of sequences—from a single sequence to an entire superfamily and shepherds them through various stages of modeling and refinement to produce simulation-ready structures. This includes comparative modeling to all relevant PDB structures (which may span multiple conformational states of interest), reconstruction of missing loops, addition of missing atoms, culling of nearly identical structures, assignment of appropriate protonation states, solvation in explicit solvent, and refinement and filtering with molecular simulation to ensure stable simulation. The output of this pipeline is an ensemble of structures ready for subsequent molecular simulations using computer clusters, supercomputers, or distributed computing projects like Folding@home. Ensembler thus automates much of the timeconsuming process of preparing protein models suitable for simulation, while allowing scalability up to entire superfamilies. A particular advantage of this approach can be found in the construction of kinetic models of conformational dynamics—such as Markov state models (MSMs)—which benefit from a diverse array of initial configurations that span the accessible conformational states to aid sampling. We demonstrate the power of this approach by constructing models for all catalytic domains in the human tyrosine kinase family, using all available kinase catalytic domain structures from any organism as structural templates.

**Ensembler** is free and open source software licensed under the GNU General Public License (GPL) v2. It is compatible with Linux and OS X. The latest release can be installed via the conda package manager, and the latest source can be downloaded from https://github.com/choderalab/ensembler.

Keywords: molecular dynamics simulation; comparative modeling; distributed simulation

### I. INTRODUCTION

Recent advances in genomics and structural biology have
helped generate an enormous wealth of protein data at
the level of amino-acid sequence and three-dimensional
structure. However, proteins typically exist as an ensemble of thermally accessible conformational states, and static
structures provide only a snapshot of their rich dynamical behavior. Many functional properties—such as the
ability to bind small molecules or interact with signaling
partners—require transitions between states, encompassing anything from reorganization of sidechains at binding interfaces to domain motions to large scale folding-unfolding
events. Drug discovery could also benefit from a more extensive consideration of protein dynamics, whereby small
molecules might be selected based on their predicted ability to bind and trap a protein target in an inactive state [1].

Molecular dynamics (MD) simulations have the capability, in principle, to describe the time evolution of a protein in atomistic detail, and have proven themselves to be a useful tool in the study of protein dynamics. A number of mature software packages and forcefields are now available, and much recent progress has been driven by advances in computing architecture. For example, many MD

29 packages are now able to exploit GPUs [2, 3], which pro-30 vide greatly improved simulation efficiency per unit cost relative to CPUs, while distributed computing platforms such as Folding@home [4], Copernicus [5, 6], and GPUGrid [7], al-33 low scalability on an unprecedented level. In parallel, meth-34 ods for building human-understandable models of protein 35 dynamics from noisy simulation data, such as Markov state modeling (MSM) approaches, are now reaching maturity [8– <sub>37</sub> 10]. MSM methods in particular have the advantage of be-38 ing able to aggregate data from multiple independent MD 39 trajectories, facilitating parallelization of production simu-40 lations and thus greatly alleviating overall computational 41 cost. There also exist a number of mature software packages 42 for comparative modeling of protein structures, in which a 43 target protein sequence is modeled using one or more struc-44 tures as templates [11, 12].

However, it remains difficult for researchers to exploit the full variety of available protein sequence and structural data in simulation studies, largely due to limitations in software architecture. For example, the set up of a biomolecular simulation is typically performed manually, encompassing a series of fairly standard (yet time-consuming) steps such as the choice of protein sequence construct and starting structure(s), addition of missing residues and atoms, solvation with explicit water and counterions (and potentially buffer components and cosolvents), choice of simulation parameters (or parameterization schemes for components where parameters do not yet exist), system relaxation with energy

<sup>\*</sup> Corresponding author; john.chodera@choderalab.org

57 minimization, and one or more short preparatory MD sim- 115 tions, and which would thus be unconnected with the phase cell. Due to the laborious and manual nature of this process, simulation studies typically consider only one or a few proteins and starting configurations. Worse still, studies (or collections of studies) that do consider multiple proteins often suffer from the lack of consistent best practices in this preparation process, making comparisons between related proteins unnecessarily difficult.

The ability to fully exploit the large quantity of available protein sequence and structural data in biomolecular simulation studies could open up many interesting avenues for research, enabling the study of entire protein families or superfamilies within a single organism or across multiple organisms. The similarity between members of a given protein family could be exploited to generate arrays of conformational models, which could be used as starting configurations to aid sampling in MD simulations. This approach ould be highly beneficial for many MD methods, such as MSM construction, which require global coverage of the conformational landscape to realize their full potential, and would also be particularly useful in cases where structural data is present for only a subset of the members of a protein family. It would also aid in studying protein families known to have multiple metastable conformations—such as kinases—for which the combined body of structural data for the family may cover a large range of these conformations, while the available structures for any individual member might encompass only one or two distinct conformations.

Here, we present the first steps toward bridging the gap between biomolecular simulation software and omicsscale sequence and structural data: a fully automated open source framework for building simulation-ready protein models in multiple conformational substates scalable from single sequences to entire superfamilies. Ensembler pro- 142 tein sequences—the sequences for which the user is invides functions for selecting target sequences and homolo- 143 terested in generating simulation-ready structural models. gous template structures, and (by interfacing with a number of external packages) performs pairwise alignments, comparative modeling of target-template pairs, and several stages of model refinement. As an example application, we 147 have constructed models for the entire set of human tyro- 148 formatted text file containing the desired target sequences sine kinase (TK) catalytic domains, using all available struc- 149 with corresponding arbitrary identifiers. tures of protein kinase domains (from any species) as templates. This results in a total of almost 400,000 models, and we demonstrate that these provide wide-ranging coverage of known functionally relevant conformations. By us- 153 via a UniProt search query. To retrieve target sequences ing these models as starting configurations for highly par- 154 from UniProt, the subcommand gather\_targets is used allel MD simulations, we expect their structural diversity to 155 with the --query flag followed by a UniProt query string greatly aid in sampling of conformational space. We further 156 conforming to the same syntax as the search function suggest that models with high target-template sequence 157 available on the UniProt website. For example, --query states, while lower sequence identity models would aid 159 man Src sequence, while the query shown in Box 1 would in sampling of more distant regions of accessible phase 160 select all human tyrosine protein kinases which have been space. It is also important to note that some models (es- 161 reviewed by a human curator. In this way, the user may sepecially low sequence identity models) may not represent 162 lect a single protein, many proteins, or an entire superfamnatively accessible conformations. However, MSM meth- 163 ily from UniProt. The program outputs a FASTA file, setting ods benefit from the ability to remove outlier MD trajec- 164 the UniProt mnemonic (e.g. SRC\_HUMAN) as the identifier for 114 tories which start from non-natively accessible conforma- 165 each target protein.

ulations to equilibrate the system and relax the simulation 116 space sampled in other trajectories. These methods essentially identify the largest subset of Markov nodes which con-118 stitute an ergodic network [13, 14].

> We anticipate that **Ensembler** will prove to be useful in 120 a number of other ways. For example, the generated models could represent valuable data sets even without subsequent production simulation, allowing exploration of the 123 conformational diversity present within the available structural data for a given protein family. Furthermore, the automation of simulation set up provides an excellent opportunity to make concrete certain "best practices", such as the 127 choice of simulation parameters.

### **DESIGN AND IMPLEMENTATION**

Ensembler is written in Python, and can be used via a 130 command-line tool (ensembler) or via a flexible Python 131 API to allow integration of its components into other 132 applications. All command-line and API information in 133 this article refers to the version 1.0 release of Ensembler. Up-to-date documentation can be found at ensembler.readthedocs.org.

The **Ensembler** modeling pipeline comprises a series of 137 stages which are performed in a defined order. A visual overview of the pipeline is shown in Fig. 1. The various stages of this pipeline are described in detail below.

# Target selection and retrieval

The first stage entails the selection of a set of target pro-144 This may be a single sequence—such as a full-length protein or a construct representing a single domain—or a collection of sequences, such as a particular domain from an entire family of proteins. The output of this stage is a FASTA-

145

146

The ensembler command-line tool allows targets to be selected from UniProt—a freely accessible resource for protein sequence and functional data (uniprot.org) [15] identity are the most likely to represent native metastable  $_{\scriptscriptstyle 158}$  ' ${\tt mnemonic:SRC\_HUMAN}$ ' would select the full-length hu-

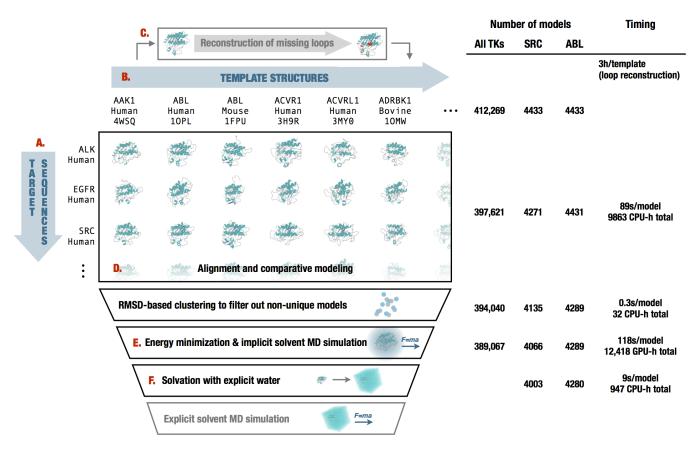

FIG. 1. Diagrammatic representation of the stages of the Ensembler pipeline and illustrative statistics for modeling all human tyrosine kinase catalytic domains. On the left, the various stages of the Ensembler pipeline are shown. The red labels indicate the corresponding text description provided for each stage in the Design and Implementation section. On the right, the number of viable models surviving each stage of the pipeline is shown for the 93 target TK domains and for two representative individual TK domains (SRC and ABL). Typical timings on a computer cluster (containing Intel Xeon E5-2665 2.4GHz hyperthreaded processors and NVIDIA GTX-680 or GTX-Titan GPUs) is reported to illustrate resource requirements per model for modeling the entire set of tyrosine kinases. Note that CPU-h denotes the number of hours consumed by the equivalent of a single CPU hyperthread and GPU-h on a single GPU—parallel execution via MPI reduces wall clock time nearly linearly.

In many cases, it will be desirable to build models of an 187 isolated protein domain, rather than the full-length protein. The gather\_targets subcommand allows protein domains to be selected from UniProt data by passing a regular expression string to the --uniprot\_domain\_regex flag. For example, the above --query flag for selecting all human protein kinases returns UniProt entries with domain annotations including "Protein kinase", "Protein kinase 1", Protein kinase 2", "Protein kinase; truncated", "Protein kinase; inactive", "SH2", "SH3", etc. The regular expression shown in Box 1 selects only domains of the first three types. If the --uniprot\_domain\_regex flag is used, target identifiers are set with the form [UniProt mnemonic]\_D[domain index], where the latter part represents a 0-based index for the domain—necessary because a single target protein may contain multiple domains of interest (e.g. JAK1\_HUMAN\_DO, 181 JAK1\_HUMAN\_D1).

another program) by providing a FASTA-formatted text file 204 186 arbitrary identifiers.

#### Template selection and retrieval

**Ensembler** uses comparative modeling to build models, and as such requires a set of structures to be used as templates. The second stage thus entails the selection of templates and storage of associated sequences, structures, and 192 identifiers. These templates can be specified manually, or using the ensembler gather\_templates subcommand to <sub>194</sub> automatically select templates based on a search of the 195 Protein Data Bank (PDB) or UniProt. A recommended approach is to select templates from UniProt which belong to 197 the same protein family as the targets, guaranteeing some degree of homology between targets and templates.

The ensembler gather\_templates subcommand pro-200 vides methods for selecting template structures from either 201 UniProt or the PDB (http://www.rcsb.org/pdb), speci-202 fied by the --gather\_from flag. Both methods select tem-Target sequences can also be defined manually (or from 203 plates at the level of PDB chains—a PDB structure containing multiple chains with identical sequence spans (e.g. for containing the desired target sequences with corresponding 205 crystal unit cells with multiple asymmetric units) would thus 206 give rise to multiple template structures.

Selection of templates from the PDB simply requires 262 residue spans are modeled in the subsequent stage. passing a list of PDB IDs as a comma-separated string, e.g. --query 2H8H,1Y57. Specific PDB chain IDs can optionally also be selected via the --chainids flag. The program retrieves structures from the PDB server, as well as associated data from the SIFTS service (www.ebi.ac.uk/pdbe/docs/sifts) [16], which provides residue-level mappings between PDB and UniProt entries. The SIFTS data is used to extract template sequences. retaining only residues which are resolved and match the equivalent residue in the UniProt sequence—nonwildtype residues are thus removed from the template structures. Furthermore, PDB chains with less than a given percentage of resolved residues (default: 70%) are filtered out. Sequences are stored in a FASTA file, with identifiers of the form [UniProt mnemonic]\_D[UniProt domain index]\_[PDB ID]\_[PDB chain ID], SRC\_HUMAN\_DO\_2H8H\_A. Matching residues then tracted from the original coordinate files and stored as PDB-format coordinate files.

Selection of templates from UniProt proceeds in a similar fashion as for target selection; the --query flag is used to select full-length proteins from UniProt, while the optional -uniprot\_domain\_regex flag allows selection of individual domains with a regular expression string (Box 1). The returned UniProt data for each protein includes a list of associated PDB chains and their residue spans, and this information is used to select template structures, using the same method as for template selection from the PDB. Only structures solved by X-ray crystallography or NMR are selected, thus excluding computer-generated models available from the PDB. If the --uniprot\_domain\_regex flag is used, then templates are truncated at the start and end of the domain

Templates can also be defined manually. Manual specification of templates simply requires storing the sequences and arbitrary identifiers in a FASTA file, and the structures as PDB-format coordinate files with filenames matching the identifiers in the sequence file. The structure residues must also match those in the sequence file.

# **Template refinement**

247

the loopmodel tool of the Rosetta software suite [17, 18]. 306 different alignment methods on model quality. We expect that in certain cases, pre-building template loops 307 with Rosetta loopmodel prior to the main modeling stage 308 minimize file storage requirements, Ensembler uses the structure; the subsequent modeling step thus automati- 312 ditional refinement schemes, and **Ensembler** thus provides but otherwise falls back to using the non-remodeled ver- 314 ally saving these restraints to file. This option is turned off by sion. Furthermore, the Rosetta loopmodel program will not 315 default, as the restraint files are relatively large (e.g.  $\sim$ 400

#### Modeling

In the modeling stage, structural models of the target se-265 quence are generated from the template structures, with 266 the goal of modeling the target in a variety of conforma-267 tions that could be significantly populated under equilib-268 rium conditions.

Modeling is performed using the automodel function of 270 the MODELLER software package [19, 20] to rapidly gener-271 ate a single model of the target sequence from each tem-272 plate structure. MODELLER uses simulated annealing cy-273 cles along with a minimal forcefield and spatial restraints generally Gaussian interatomic probability densities extracted from the template structure with database-derived statistics determining the distribution width—to rapidly generate candidate structures of the target sequence from the provided template sequence [19, 20].

While MODELLER's automodel function can generate its own alignments automatically, a standalone function was preferable for reasons of programming convenience. As 282 such, we implemented pairwise alignment functionality using the BioPython pairwise2 module [21]—which uses a dynamic programming algorithm—with the PAM 250 scor-285 ing matrix of Gonnet et al. [22]. The alignments are carried out with the align subcommand, prior to the model-287 ing step which is carried out with the build\_models sub-288 command. The align subcommand also writes a list of 289 the sequence identities for each template to a text file, 290 and this can be used to select models from a desired 291 range of sequence identities. The build\_models sub-292 command and all subsequent pipeline functions have a --template\_seqid\_cutoff flag which can be used to select only models with sequence identities greater than the given value. We also note that alternative approaches could be used for the alignment stage. For example, multiple sequence alignment algorithms [23], allow alignments to be guided using sequence data from across the entire protein family of interest, while (multiple) structural alignment algorithms such as MODELLER's salign routine [19, 20], PRO-MALS3D [24], and Expresso and 3DCoffee [25, 26], can additionally exploit structural data. **Ensembler's** modular archi-Unresolved template residues can optionally be modeled 303 tecture facilitates the implementation of alternative aligninto template structures with the loopmodel subcommand, 304 ment approaches, and we plan to implement some of these which employs a kinematic closure algorithm provided via 305 in future versions, to allow exploration of the influence of

### Filtering of nearly identical models

Because **Ensembler** treats individual chains from source PDB structures as individual templates, a number of models may be generated with very similar structures if these individual chains are nearly identical in conformation. For this reason, and also to allow users to select for high diersity if they so choose, **Ensembler** provides a way to filter out models that are very similar in RMSD. The cluster subcommand can thus be used to identify models which differ from other models in terms of RMSD distance by a userspecified cutoff. Clustering is performed using the regular spatial clustering algorithm [9], as implemented in the MSM-Builder Python library [13], which uses mdtraj [27] to calculate RMSD (for  $C_{\alpha}$  atoms only) with a fast quaternion characteristic polynomial (QCP) [28-30] implementation. A minimum distance cutoff (which defaults to 0.6 Å) is used to retain only a single model per cluster.

#### **Refinement of models**

tion [32].

water molecules, if desired.

the vast majority failed within the first 1 ps of simulation.

368 have been chosen to represent current "best practices" 421 solvent MD refinement.

369 for the refinement simulations carried out here. As such, the simulation is performed using Langevin dynamics, with a default force field choice of Amber99SB-ILDN [35], along with a modified generalized Born solvent model [36] as implemented in the OpenMM package [2]. Any of the other force fields or implicit water models implemented in OpenMM can be specified using the --ff and --water\_model flags respectively. The simulation length can also be controlled via the --simlength flag, and many 378 other important simulation parameters can be controlled from either the API or CLI (via the --api\_params flag). The 380 default values are set as follows—timestep: 2 fs; temper-381 ature: 300 K; Langevin collision rate: 20 ps $^{-1}$ ; pH (used 382 by OpenMM for protonation state assignment): 7. We also 383 draw attention to a recent paper which indicates that lower Langevin collision rates may result in faster phase space ex-<sub>385</sub> ploration [37].

## Solvation and NPT equilibration

While protein-only models may be sufficient for struc-388 tural analysis or implicit solvent simulations, Ensembler A number of refinement methods have been developed to also provides a stage for solvating models with explicit waelp guide comparative modeling techniques toward more 390 ter and performing a round of explicit-solvent MD refinenative-like" and physically consistent conformations [31, 391 ment/equilibration under isothermal-isobaric (NPT) condi-32], of which MD simulations are an important example. 392 tions. The solvation step solvates each model for a given While long-timescale unrestrained MD simulations (on the 393 target with the same number of waters to facilitate the inorder of 100  $\mu$ s) have been found to be ineffective for recapit-  $_{394}$  tegration of data from multiple simulations, which is imporulating native-like conformations, possibly due to forcefield 395 tant for methods such as the construction of MSMs. The issues [33], even relatively short simulations can be useful 396 target number of waters is selected by first solvating each for relaxing structural elements such as sidechain orienta- 397 model with a specified padding distance (default: 10 Å), then taking a percentile value from the distribution (default: Ensembler thus includes a refinement module, which 399 68th percentile). This helps to prevent models with paruses short molecular dynamics simulations to refine the 400 ticularly long, extended loops—such as those arising from models built in the previous step. As well as improving 401 template structures with unresolved termini—from imposmodel quality, this also prepares models for subsequent 402 ing very large box sizes on the entire set of models. The production MD simulation, including solvation with explicit 403 TIP3P water model [38] is used by default, but any of the 404 other explicit water models available in OpenMM, such as Models are first subjected to energy minimization (using 405 TIP4P-Ew [39], can be specified using the --water\_model the L-BFGS algorithm [34], followed by a short molecular 406 flag. Models are resolvated with the target number of wadynamics (MD) simulation with an implicit solvent repre- 407 ters by first solvating with zero padding, then incrementally sentation. This is implemented using the OpenMM molecu- 408 increasing the box size and resolvating until the target is exlar simulation toolkit [2], chosen for its flexible Python API, 409 ceeded, then finally deleting sufficient waters to match the and high performance GPU-acclerated simulation code. The module could easily be extended to add methods for preparing models for other purposes. For example, production simulations could alternatively be run using Copernicus [5, 6]—a framework for performing parallel adaptive MD simulations— 435 or GPUGrid [7]—a distributing computing platform which <sup>436</sup> relies on computational power voluntarily donated by the owners of nondedicated GPU-equipped computers.

#### Other features

#### Tracking provenance information

To aid the user in tracking the provenance of each model, each pipeline function also outputs a metadata file, which helps to link data to the software version used to generate it (both Ensembler and its dependencies), and also provides timing and performance information, and other data such as hostname.

## Rapidly modeling a single template

For users interested in simply using **Ensembler** to rapidly generate a set of models for a single template sequence, En**sembler** provides a command-line tool quickmodel, which performs the entire pipeline for a single target with a small number of templates. For larger numbers of models (such as entire protein families), modeling time is greatly reduced by using the main modeling pipeline, which is parallelized via MPI, distributing computation across each model (or across each template, in the case of the loop reconstruction code), and scaling (in a "pleasantly parallel" manner) up to the number of models generated.

### RESULTS

## Modeling of all human tyrosine kinase catalytic domains

As a first application of **Ensembler**, we have built mod-460 461 els for the human TK family. TKs (and protein kinases in general) play important roles in many cellular processes and are involved in a number of types of cancer [40]. For example, a translocation between the TK Abl1 and the pseudok- 519 Abl1). inase Bcr is closely associated with chronic myelogenous 520

467 colon, breast, prostate, lung, and pancreatic cancers [42]. 468 Protein kinase domains are thought to have multiple acces-Ensembler provides a packaging module which 469 sible metastable conformation states, and much effort is di-The 470 rected at developing kinase inhibitor drugs which bind to package\_models subcommand currently provides func- 471 and stabilize inactive conformations [43]. Kinases are thus tions (specified via the --package\_for flag) for com- 472 a particularly interesting subject for study with MSM methods [44], and this approach stands to benefit greatly from the ability to exploit the full body of available genomic and structural data within the kinase family, e.g. by generating 476 large numbers of starting configurations to be used in highly 477 parallel MD simulation.

We selected all human TK domains annotated in UniProt as targets, and all available structures of protein kinase do-480 mains (of any species) as templates, using the commands shown in Box 1. This returned 93 target sequences and 4433 template structures, giving a total of 412,269 targettemplate pairs. The templates were derived from 3028 indi-484 vidual PDB entries and encompassed 23 different species, with 3634 template structures from human kinase constructs.

The resultant models are available as part of a supplementary dataset which can be downloaded from the Dryad 489 Digital Repository (DOI: 10.5061/dryad.7fg32).

#### **Ensembler modeling statistics**

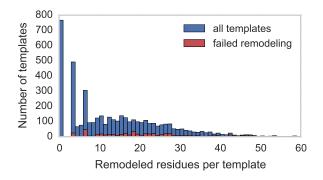

Crystallographic structures of kinase catalytic domains generally contain a significant number of missing residues (median 11, mean 14, standard deviation 13, max 102) due to the high mobility of several loops (Fig. 2, top), with a number of these missing spans being significant in length (median 5, mean 7, standard deviation 6, max 82; Fig. 2, bottom). To reduce the reliance on the MODELLER rapid model construction stage to reconstruct very long unresolved loops, unresolved template residues were first remodeled using the 100pmodel subcommand. Out of 3666 templates with one or more missing residues, 3134 were successfully remod-502 eled by the Rosetta loop modeling stage (with success de-503 fined simply as program termination without error); most remodeling failures were attributable to unsatisfiable spa-505 tial constraints imposed by the original template structure. There was some correlation between remodeling failures and the number of missing residues (Fig. 2, top); templates for which remodeling failed had a median of 20 missing residues, compared to a median of 14 missing residues for templates for which remodeling was successful.

Following loop remodeling, the **Ensembler** pipeline was performed up to and including the implicit solvent MD refinement stage, which completed with 389,067 (94%) surviving models across all TKs. To obtain statistics for the solvation stage without generating a sizeable amount of coor-516 dinate data (with solvated PDB coordinate files taking up si7 about 0.9 MB each), the solvate subcommand was per-518 formed for two representative individual kinases (Src and

ensembler gather_templates --gather_from uniprot --query 'domain: "Protein kinase" AND reviewed: yes
                           --uniprot_domain_regex '^Protein kinase(?!; truncated)(?!; inactive)'
```

Box 1. Ensembler command-line functions used to select targets and templates. The commands retrieve target and template data by querying UniProt. The query string provided to the gather\_targets command selects all human tyrosine protein kinases which have been reviewed by a curator, while the query string provided to the gather\_templates command selects all reviewed protein kinases of any species. The --uniprot\_domain\_regex flag is used to select a subset of the domains belonging to the returned UniProt protein entries, by matching the domain annotations against a given regular expression. In this example, domains of type "Protein kinase", "Protein kinase 1", and "Protein kinase 2" were selected, while excluding many other domain types such as "Protein kinase; truncated", "Protein kinase; inactive", "SH2", "SH3", etc. Target selection simply entails the selection of sequences corresponding to each matching UniProt domain. Template selection entails the selection of the sequences and structures of any PDB entries corresponding to the matching UniProt domains.

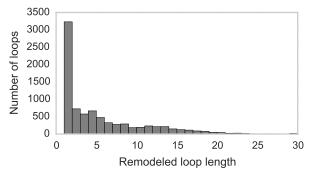

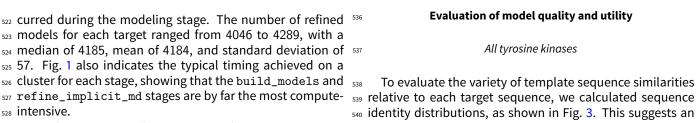

FIG. 2. Distributions for the number of missing residues in the **TK templates.** The upper histograms show the number of missing residues per template, for all templates (blue) and for only those templates for which template remodeling with the loopmodel subcommand failed (red). The lower histogram shows the number of residues in each missing loop, for all templates.

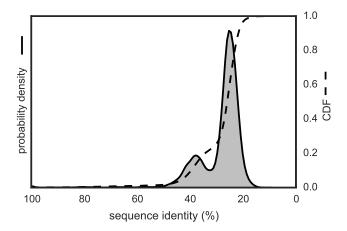

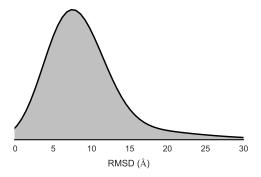

FIG. 3. Template-target sequence identity distribution for human tyrosine kinase catalytic domains. Sequence identities are calculated from all pairwise target-template alignments, where targets are human kinase catalytic domain sequences and templates are all kinase catalytic domains from any organism with structures in the PDB, as described in the text. A kernel density estimate of the target-template sequence identity probability density function is shown as a solid line with shaded region, while the corresponding cumulative distribution function is shown as a dashed

533 output from the modeling stage (without saving MODELLER restraints files, which are about 397 kB per model) and 77 kB 535 for the implicit solvent MD refinement stage.

## **Evaluation of model quality and utility**

# All tyrosine kinases

To evaluate the variety of template sequence similarities 540 identity distributions, as shown in Fig. 3. This suggests an The files generated for each model (up to and including 541 intuitive division into three categories, with 355,712 modthe implicit solvent MD refinement stage) totaled ~116 kB in 542 els in the 0-35% sequence identity range, 51,330 models in size, totalling 0.5 GB per TK target or 42 GB for all 93 targets. 543 the 35–55% range, and 5227 models in the 55–100% range. The data generated per model breaks down as 39 kB for the 544 We then computed the RMSD distributions for the models

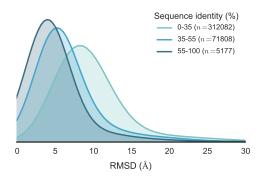

FIG. 4. Distribution of RMSDs to all TK catalytic domain models relative to the model derived from the highest sequence identity template. Distributions are built from data from all 93 TK do- 567 main targets. To better illustrate how conformational similarity depends on sequence identity, the lower plot illustrates the distributions as stratified into three sequence identity classes: high identity (55-100%), moderate identity (35-55%), and remote identity (0-35%). The plotted distributions have been smoothed using kernel density estimation.

created for each target (relative to the model derived from the template with highest sequence identity) Fig. 4, to assess the diversity of conformations captured by the modeling pipeline. Furthermore, to understand the influence of sequence identity on the conformational similarities of the resulting models, the RMSD distributions were stratified based on the three sequence identity categories described above. This analysis indicates that higher sequence identity templates result in models with lower RMSDs, while templates with remote sequence identities result in larger RMSDs on average.

at the end of the implicit solvent MD refinement stage. 587 based on the sequence identity between the target and temranges as above—are plotted in Fig. 5, indicating that higher 592 entation. sequence identity templates tend to result in slightly lower 593 energy models. Of the 4973 models which failed to complete 594 identity model with a long unstructured region at one of 565 the implicit refinement MD stage, all except 9 failed within 595 the termini, which was unresolved in the original template

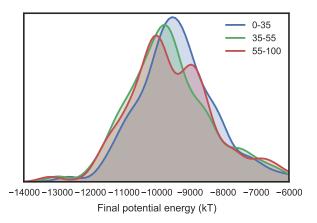

FIG. 5. Distribution of final energies from implicit solvent MD refinement of TK catalytic domain models. To illustrate how the energies are affected by sequence identity, the models are separated into three sequence identity classes: high identity (55–100%). moderate identity (35-55%), and remote identity (0-35%). The plotted distributions have been smoothed using kernel density estimation. Refinement simulations were carried out at the default temperature of 300 K.

the first 1 ps of simulation.

#### Src and Abl1

To provide a more complete evaluation of the models generated, we have analyzed two example TKs (Src and Abl1) 570 in detail. Due to their importance in cancer, these kinases 571 have been the subject of numerous studies, encompassing 572 many different methodologies. In terms of structural data, <sub>573</sub> a large number of crystal structures have been solved (with or without ligands such as nucleotide substrate or inhibitor drugs), showing the kinases in a number of different conformations. These two kinases are thus also interesting targets 577 for MSM studies, with one recent study focusing on mod-578 eling the states which constitute the activation pathway of 579 Src [44].

Fig. 6 shows a superposition of a set of representative models of Src and Abl1. Models were first stratified into three ranges, based on the structure of the sequence identity distribution (Fig. 3), then subjected to RMSD-based k-medoids 584 clustering (using the msmbuilder clustering package [13]) to pick three representative models from each sequence iden-We also analyzed the potential energies of the models 586 tity range. Each model is colored and given a transparency These ranged from -14180 kT to -3160 kT, with a median 588 plate sequence. The figure gives an idea of the variance of -9501 kT, mean of -9418 kT, and a standard deviation 589 present in the generated models. High sequence identity of 1198 kT (with a simulation temperature of 300 K). The 590 models (in opaque blue) tend to be quite structurally simdistributions—stratified using the same sequence identity 591 ilar, with some variation in loops or changes in domain ori-

The Abl1 renderings in Fig. 6 indicate one high sequence

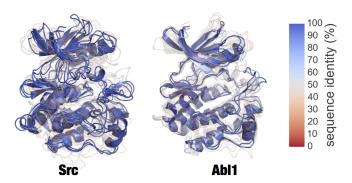

FIG. 6. Superposition of clustered models of Src and Abl1. Superposed renderings of nine models each for Src and Abl1, giving some indication the diversity of conformations generated by Ensembler. The models for each target were divided into three sequence identity ranges (as in Fig. 4), and RMSD-based k-medoids clustering was performed (using the msmbuilder clustering package [13]) to select three clusters from each. The models shown are the centroids of each cluster. Models are colored and given transparency based on their sequence identity, so that high sequence identity models are blue and opaque, while lower sequence identity models are transparent and red.

landscape. The high sequence identity models could be 641 evant conformational states. considered to be the most likely to accurately represent true metastable states. Conversely, the lower sequence identity models could be expected to help push a simulation into regions of conformation space which might take intractably long to reach if starting a single metastable conformation.

610

To evaluate the models of Src and Abl1 in the context of the 643 published structural biology literature on functionally relevant conformations, we have focused on two residue pair 644 distances thought to be important for the regulation of pro- 645 tive open source software development platform GitHub tein kinase domain activity. We use the residue number- 646 (github.com/choderalab/ensembler). The latest release can ing schemes for chicken Src (which is commonly used in the 647 be installed via the conda package manager for Python literature even in reference to human Src) [45, 46] and hu- 648 (conda.pydata.org), using the two commands shown in man Abl1 isoform A [47-49] respectively; the exact number- 649 Box 2. sent inactive (PDB code: 2SRC) [45] and active (PDB code: 652 arately by the user. The latest source can be downloaded 1Y57) [46] states. One notable feature which distinguishes 653 from the GitHub repository, which also contains up-to-date the two structures is the transfer of an electrostatic interac- 654 instructions for building and installing the code. Documention of E310 from R409 (in the inactive state) to K295 (in the 655 tation can be found at ensembler.readthedocs.org. active state), brought about by a rotation of the  $\alpha$ C-helix. 656 These three residues are also well conserved [50], and a 657 the Dryad Digital Repository (DOI: 10.5061/dryad.7fg32). number of experimental and simulation studies have sug- 658 This contains the TK models described in the III section, gengested that this electrostatic switching process plays a role 659 eral information on the targets and templates, plus a script

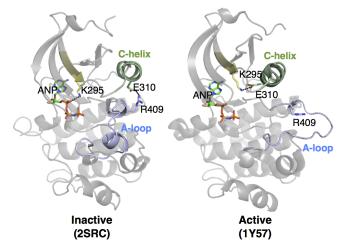

FIG. 7. Two structures of Src, indicating certain residues involved in activation. In the inactive state, E310 forms a salt bridge with R409. During activation, the  $\alpha$ C-helix (green) moves and rotates, orienting E310 towards the ATP-binding site and allowing it to instead form a salt bridge with K295. This positions K295 in the appropriate position for catalysis.

structure. While such models are not necessarily incorrect [63] family [44, 51, 52]. As such, we have projected the Ensemor undesirable, it is important to be aware of the effects they 632 **bler** models for Src and Abl1 onto a space consisting of the may have on production simulations performed under peri- 633 distances between these two residue pairs (Fig. 8). The mododic boundary conditions, as long unstructured termini can 634 els show strong coverage of regions in which either of the be prone to interact with a protein's periodic image. Lower 635 electrostatic interactions is fully formed (for models across sequence identity models (in transparent white or red) in- 636 all levels of target-template sequence identity), as well as a dicate much greater variation in all parts of the structure. 637 wide range of regions in-between (mainly models with low We believe the mix of high and low sequence identity mod- 638 sequence identity). We thus expect that such a set of models to be particularly useful for methods such as MSM build- 639 els, if used as starting configurations for highly parallel MD ing, which require thorough sampling of the conformational 640 simulation, could greatly aid in sampling of functionally rel-

## **AVAILABILITY AND FUTURE DIRECTIONS**

### **Availability**

The code for **Ensembler** is hosted on the collabora-650 ELLER and Rosetta, which are not available through the Fig. 7 shows two structures of Src believed to repre- 651 conda package manager, and thus must be installed sep-

A supplementary dataset can also be downloaded from in a regulatory mechanism shared across the protein kinase 600 and instructions for regenerating the same dataset.

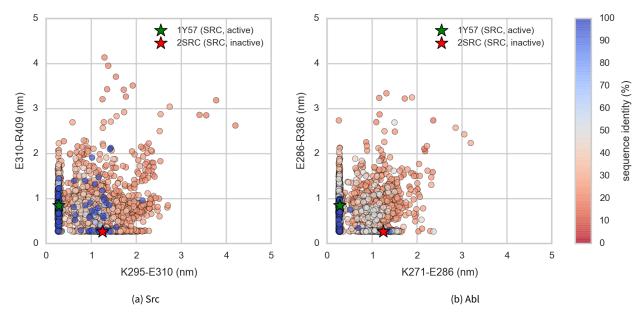

FIG. 8. Src and Abl1 models projected onto the distances between two conserved residue pairs, colored by sequence identity. Two Src structures (PDB entries 1Y57 [46] and 2SRC [45]) are projected onto the plots for reference, representing active and inactive states respectively. These structures and the residue pairs analyzed here are depicted in Fig. 7. Distances are measured between the center of masses of the three terminal sidechain heavy atoms of each residue. The atom names for these atoms, according to the PDB coordinate files for both reference structures, are—Lys: NZ, CD, CE (ethylamine); Glu: OE1, CD, OE2 (carboxylate); Arg: NH1, CZ, NH2 (part of guanidine).

conda config -add channels https://conda.binstar.org/omnia conda install ensembler

Box 2. Ensembler installation using conda.

# **Future Directions**

661

Comparative protein modeling and MD simulation set-up can be approached in a number of different ways, with varying degrees of complexity, and there are a number of obviment in future versions of Ensembler.

683 for assigning protonation states with MCCE2 [55–57], which 713 ity.

uses electrostatics calculations combined with Monte Carlo sampling of side chain conformers to calculate pKa values.

Many proteins require the presence of various types of non-protein atoms and molecules for proper function, such as metal ions (e.g.  $Mg^{+2}$ ), cofactors (e.g. ATP) or posttranslational modifications (e.g. phosphorylation, methylation, glycosylation, etc.), and we thus plan for Ensembler to eventually have the capability to include such entities in the generated models. Binding sites for metal ions are frequently found in proteins, often playing a role in catalysis. For example, protein kinase domains contain two bindous additions and improvements which we plan to imple- 695 ing sites for divalent metal cations, and display significantly 696 increased activity in the presence of Mg<sup>2+</sup> [58], the diva-Some amino acids can exist in different protonation 697 lent cation with highest concentration in mammalian cells. 668 states, depending on pH and on their local environment. 698 Metal ions are often not resolved in experimental structures These protonation states can have important effects on bi- of proteins, but by taking into account the full range of availological processes. For example, long timescale MD simula- 700 able structural data, it should be possible in many cases tions have suggested that the conformation of the DFG mo- 701 to include metal ions based on the structures of homolotif of the TK Abl1—believed to be an important regulatory 702 gous proteins. We are careful to point out, however, that mechanism [53]—is controlled by protonation of the aspar- 703 metal ion parameters in classical MD force fields have signiftate [54]. Currently, protonation states are assigned simply 104 icant limitations, particularly in their interactions with probased on pH (a user-controllable parameter). At neutral pH, 705 teins [59]. Cofactors and post-translational modifications histidines have two protonation states which are approxi- 706 are also often not fully resolved in experimental structures, mately equally likely, and in this situation the selection is 101 and endogenous cofactors are frequently substituted with therefore made based on which state results in a better hy- 708 other molecules to facilitate experimental structural analydrogen bond. It would be highly desirable to instead use a 709 sis. Again, **Ensembler** could exploit structural data from a method which assigns amino acid protonation states based 710 set of homologous proteins to model in these molecules, alon a rigorous assessment of the local environment. We thus multiple though there will likely be a number of challenges to overplan to implement an interface and command-line function 712 come in the design and implementation of such functionalinvolves the treatment of members of a protein family with 736 community. especially long residue insertions or deletions. For example, the set of all human protein kinase domains listed in UniProt have a median length of 265 residues (mean 277) and a 137 standard deviation of 45, yet the minimum and maximum lengths are 102 and 801 respectively. The latter value corresponds to the protein kinase domain of serine/threoninekinase *greatwall*, which includes a long insertion between the two main lobes of the catalytic domain. In principle, such insertions could be excluded from the generated models, though a number of questions would arise as to how best to approach this.
