The rapidly expanding body of available genomic and protein structural data provides a rich resource for understanding protein dynamics with biomolecular simulation. While computational infrastructure has grown rapidly, simulations on an omics scale are not yet widespread, primarily because software infrastructure to enable simulations at this scale has not kept pace. It should now be possible to study protein dynamics across entire (super)families, exploiting both available structural biology data and conformational similarities across homologous proteins. Here, we present a new tool for enabling high-throughput simulation in the genomics era. Ensembler takes any set of sequences—from a single sequence to an entire superfamily and shepherds them through various stages of modeling and refinement to produce simulation-ready structures. This includes comparative modeling to all relevant PDB structures (which may span multiple conformational states of interest), reconstruction of missing loops, addition of missing atoms, culling of nearly identical structures, assignment of appropriate protonation states, solvation in explicit solvent, and refinement and filtering with molecular simulation to ensure stable simulation. The output of this pipeline is an ensemble of structures ready for subsequent molecular simulations using computer clusters, supercomputers, or distributed computing projects like Folding@home. Ensembler thus automates much of the timeconsuming process of preparing protein models suitable for simulation, while allowing scalability up to entire superfamilies. A particular advantage of this approach can be found in the construction of kinetic models of conformational dynamics—such as Markov state models (MSMs)—which benefit from a diverse array of initial configurations that span the accessible conformational states to aid sampling. We demonstrate the power of this approach by constructing models for all catalytic domains in the human tyrosine kinase family, using all available kinase catalytic domain structures from any organism as structural templates.

**Ensembler** is free and open source software licensed under the GNU General Public License (GPL) v2. It should run on all major operating systems, and has been tested on Linux and OS X. The latest release can be installed via the conda package manager, and the latest source can be downloaded from <a href="https://github.com/choderalab/ensembler">https://github.com/choderalab/ensembler</a>.

Keywords: molecular dynamics simulation; comparative modeling; distributed simulation

# I. INTRODUCTION

Recent advances in genomics and structural biology have helped generate an enormous wealth of protein data at the level of amino-acid sequence and three-dimensional structure. However, proteins typically exist as an ensemble of thermally accessible conformational states, and static structures provide only a snapshot of their rich dynamical behavior. Many functional properties—such as the ability to bind small molecules or interact with signaling partners—require transitions between states, encompassing anything from reorganization of sidechains at binding interfaces to domain motions to large scale folding-unfolding events. Drug discovery could also benefit from a more extensive consideration of protein dynamics, whereby small molecules might be selected based on their predicted ability to bind and trap a protein target in an inactive state [1].

Molecular dynamics (MD) simulations have the capabilMolecular dynamics (MD) simulations have the capabilJity, in principle, to describe the time evolution of a protein in atomistic detail, and have proven themselves to be a useful tool in the study of protein dynamics. A number of mature software packages and forcefields are now available, and much recent progress has been driven by advances in computing architecture. For example, many MD

29 packages are now able to exploit GPUs [2, 3], which pro-30 vide greatly improved simulation efficiency per unit cost rel-31 ative to CPUs, while distributed computing platforms such 32 as Folding@home [4], Copernicus [5], and GPUGrid [6], al-33 low scalability on an unprecedented level. In parallel, meth-34 ods for building human-understandable models of protein 35 dynamics from noisy simulation data, such as Markov state modeling (MSM) approaches, are now reaching maturity [7– <sup>37</sup> 9]. MSM methods in particular have the advantage of be-38 ing able to aggregate data from multiple independent MD 39 trajectories, facilitating parallelization of production simu-40 lations and thus greatly alleviating overall computational 41 cost. There also exist a number of mature software packages 42 for comparative modeling of protein structures, in which a 43 target protein sequence is modeled using one or more struc-44 tures as templates [10, 11].

However, it remains difficult for researchers to exploit the full variety of available protein sequence and structural data in simulation studies, largely due to limitations in software architecture. For example, the set up of a biomolecular simulation is typically performed manually, encompassing a series of fairly standard (yet time-consuming) steps such as the choice of protein sequence construct and starting structure(s), addition of missing residues and atoms, solvation with explicit water and counterions (and potentially buffer components and cosolvents), choice of simulation parameters (or parameterization schemes for components where

<sup>\*</sup> Corresponding author; john.chodera@choderalab.org

minimization, and one or more short preparatory MD simulations to equilibrate the system and relax the simulation cell. Due to the laborious and manual nature of this process, simulation studies typically consider only one or a few proteins and starting configurations. Worse still, studies (or collections of studies) that do consider multiple proteins often suffer from the lack of consistent best practices in this preparation process, making comparisons between related proteins unnecessarily difficult.

The ability to fully exploit the large quantity of available protein sequence and structural data in biomolecular simulation studies could open up many interesting avenues for research, enabling the study of entire protein families or superfamilies within a single organism or across multiple organisms. The similarity between members of a given protein family could be exploited to generate arrays of conformational models, which could be used as starting configu- 125 rations to aid sampling in MD simulations. This approach would be highly beneficial for many MD methods, such as MSM construction, which require global coverage of the conformational landscape to realize their full potential, and would also be particularly useful in cases where structural data is present for only a subset of the members of a protein family. It would also aid in studying protein families known to have multiple metastable conformations—such as kinases—for which the combined body of structural data for the family may cover a large range of these conformations, while the available structures for any individual member might encompass only one or two distinct conformations.

Here, we present the first steps toward bridging the gap between biomolecular simulation software and omicsscale sequence and structural data: a fully automated open source framework for building simulation-ready protein models in multiple conformational substates scalable from single sequences to entire superfamilies. **Ensembler** provides functions for selecting target sequences and homologous template structures, and (by interfacing with a number of external packages) performs pairwise alignments, comparative modeling of target-template pairs, and several stages of model refinement. As an example application, we have constructed models for the entire set of human tyrosine kinase catalytic domains, using all available structures of protein kinase domains (from any species) as templates. This results in a total of almost 400,000 models, and we demonstrate that these provide wide-ranging coverage of known functionally relevant conformations. By using these models as starting configurations for highly parallel MD simulations, we expect their structural diversity to greatly aid in sampling of conformational space.

number of other ways. For example, the generated modtural data for a given protein family. Furthermore, the au- 162 "Protein kinase; inactive", "SH2", "SH3", etc. To select tomation of simulation set up provides an excellent oppor- 163 only domains of the first three types, the following reg-

#### **DESIGN AND IMPLEMENTATION**

**Ensembler** is written in Python, and can be used via a 118 command-line tool (ensembler) or via a flexible Python API 119 to allow integration of its components into other applica-120 tions.

The **Ensembler** modeling pipeline comprises a series of 122 stages which are performed in a defined order. A visual overview of the pipeline is shown in Fig. 1. The various stages of this pipeline are described in detail below.

#### Target selection and retrieval

The first stage entails the selection of a set of target protein sequences—the sequences the user is interested in gen-128 erating simulation-ready structural models for. This may be 129 a single sequence—such as a full-length protein or a con-130 struct representing a single domain—or a collection of sequences, such as a particular domain from an entire family of proteins. The output of this stage is a FASTA-formatted 133 text file containing the desired target sequences with corresponding arbitrary identifiers.

The ensembler command-line tool allows targets to 136 be selected from UniProt—a freely accessible resource for protein sequence and functional data (uniprot.org) [JDC: Cite one of these UniProt citations?]—via a UniProt search query. To retrieve target sequences from UniProt, 140 the subcommand gather\_targets us used with the --query flag followed by a UniProt query string con-142 forming to the same syntax as the search function available on the UniProt website. For example, --query 'mnemonic:SRC\_HUMAN' would select the full-length 145 human Src sequence, while --query 'domain: "Protein 146 kinase" AND taxonomy:9606 AND reviewed:yes' would select all human protein kinases which have been reviewed by a human curator. In this way, the user may select a single protein, many proteins, or an entire superfamily 150 from UniProt. The program outputs a FASTA file, setting the 151 UniProt mnemonic (e.g. SRC\_HUMAN) as the identifier for 152 each target protein.

In many cases, it will be desirable to build models of 154 an isolated protein domain, rather than the full-length 155 protein. The gather\_targets subcommand allows pro-156 tein domains to be selected from UniProt data by pass-We anticipate that the tool will prove to be useful in a 157 ing a regular expression string to the --domains flag. 158 For example, the above --query flag for selecting all els could represent valuable data sets even without sub- 159 human protein kinases returns UniProt entries with dosequent production simulation, allowing exploration of the 👊 main annotations including "Protein kinase", "Protein kiconformational diversity present within the available struc- 161 nase 1", "Protein kinase 2", "Protein kinase; truncated", 113 tunity to make concrete certain "best practices", such as the 164 ular expression could be used: 'Protein kinase(?!;

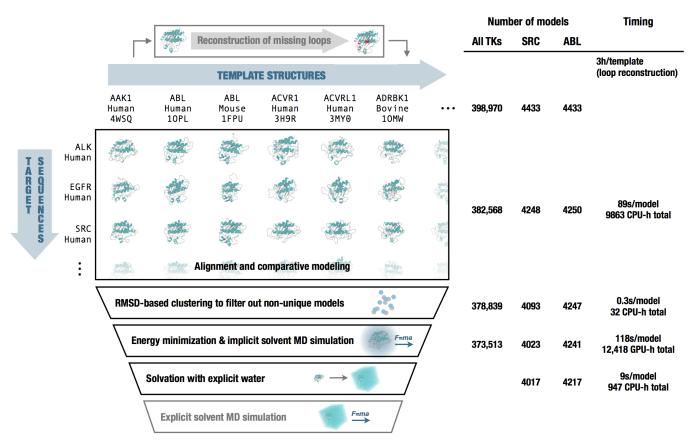

FIG. 1. Diagrammatic representation of the various stages of the Ensembler pipeline and illustrative statistics for modeling all human tyrosine kinase catalytic domains. On the left, the various stages of the Ensembler pipeline are shown. On the right, the number of viable models surviving each stage of the pipeline is shown for modeling all 90 tyrosine kinases (All TKs) and representative individual tyrosine kinases (SRC and ABL). Typical timings on a computer cluster (containing Intel Xeon E5-2665 2.4GHz hyperthreaded processors and NVIDIA GTX-680 or GTX-Titan GPUs) is reported to illustrate resource requirements per model for modeling the entire set of tyrosine kinases. Note that CPU-h denotes the number of hours consumed by the equivalent of a single CPU hyperthread and GPU-h on a single GPU—parallel execution via MPI reduces wall clock time nearly linearly.

index], where the latter part represents a 0-based index for 186 degree of homology between targets and templates. the domain—necessary because a single target protein may 197 169 JAK1\_HUMAN\_D1).

Target sequences can also be defined manually (or from 190 another program) by providing a FASTA-formatted text file containing the desired target sequences with corresponding arbitrary identifiers.

## Template selection and retrieval

175

and as such requires a set of structures to be used as tem- 199 flag.

truncated) (?!; inactive). In this case, target identi- 184 proach is to select templates from UniProt which belong to fiers are set with the form [UniProt mnemonic]\_D[domain 185 the same protein family as the targets, guaranteeing some

The ensembler gather\_templates subcommand procontain multiple domains of interest (e.g. JAK1\_HUMAN\_DO, 188 vides methods for selecting template structures from either uniProt or the PDB (http://www.rcsb.org/pdb), specified by the --gather\_from flag. Both methods select templates at the level of PDB chains—a PDB structure containing multiple chains with identical sequence spans (e.g. for crystal unit cells with multiple asymmetric units) would thus give rise to multiple template structures.

Selection of templates from the PDB simply requires 196 passing a list of PDB IDs as a comma-separated string, Specific PDB chain IDs 197 e.g. --query 2H8H,1Y57. Ensembler uses comparative modeling to build models, 198 can optionally also be selected via the --chainids The program retrieves structures from the PDB plates. The second stage thus entails the selection of tem- 200 server, as well as associated data from the SIFTS service plates and storage of associated sequences, structures, and 201 (www.ebi.ac.uk/pdbe/docs/sifts) (CITE: Velankar Nucleic identifiers. These templates can be specified manually, or 202 Acids Res 2013), which provides residue-level mappings beusing the ensembler gather\_templates subcommand to 203 tween PDB and UniProt entries. The SIFTS data is used to exautomatically select templates based on a search of the 204 tract template sequences, retaining only residues which are 183 Protein Data Bank (PDB) or UniProt. A recommended ap- 205 resolved and match the equivalent residue in the UniProt

than a given percentage of resolved residues (default: 70%) 263 residues spans are modeled in the subsequent stage. are filtered out. Sequences are stored in a FASTA file, with identifiers of the form [UniProt mnemonic]\_D[UniProt domain index]\_[PDB ID]\_[PDB chain ID], SRC\_HUMAN\_DO\_2H8H\_A. Matching residues then extracted from the original coordinate files and stored as PDB-format coordinate files.

Selection of templates from UniProt proceeds in a similar fashion as for target selection; the --query flag is used to select full-length proteins from UniProt, while the optional -domains flag allows selection of individual domains with regular expression string. The returned UniProt data for each protein includes a list of associated PDB chains and their residue spans, and this information is used to select template structures, using the same method as for template selection from the PDB. Only structures solved by X-ray crystallography or NMR are selected, thus excluding computergenerated models available from the PDB. If the --domains flag is used, then templates are truncated at the start and end of the domain sequence.

Templates can also be defined manually. Manual specifiation of templates simply requires storing the sequences and identifiers in a FASTA file, and the structures as PDBformat coordinate files with filenames matching the identifiers in the sequence file. The structure residues must also match those in the sequence file.

228

234

255

### **Template refinement**

Unresolved template residues can optionally be modeled into template structures with the loopmodel subcommand, which employs a kinematic closure algorithm provided via the loopmodel tool of the Rosetta software suite [12, 13]. Because fewer loops need to be built during the subsequent 294 target model-building stage, we find that prebuilding template loops tends to provide higher-quality models after ompletion of the **Ensembler** pipeline. [JDC: Should we cite ur evidence for this with the TKs, or maybe tone back the laim a bit to say that it is possible this could make things asier?] [DLP: Sikander mentioned to me that someone has developed an algorithm called pokefind (or knotfind, which I think is an earlier version) which aims to find knots in proteins, of the type which encouraged us to use Rosetta to reconstruct template loops. DOI: 10.1093/bioinformatics/btp198 It sounds like these algorithms have actually been implemented in Rosetta, so this could explain why Rosetta seems to do better at avoiding making these knotted strucures. Would be useful to check this out further first, and then decide whether or not to discuss the knotted structures in the manuscript.]

Loop remodeling may fail for a small proportion of templates due to spatial constraints imposed by the original 309 structure; the subsequent modeling step thus automati- 310 PDB structures as individual templates, a number of models cally uses the remodeled version of a template if available, and may be generated with very similar structures if these indibut otherwise falls back to using the non-remodeled ver- 312 vidual chains are nearly identical in conformation. For this

sequence—non-wildtype residues are thus removed from 261 sion. Furthermore, the Rosetta loopmodel program will not the template structures. Furthermore, PDB chains with less 262 model missing residues at the termini of a structure—such

#### Modeling

In the modeling stage, structural models of the target se-266 quence are generated from the template structures, with the goal of modeling the target in a variety of conforma-268 tions that could be significantly populated under equilibrium conditions.

Modeling is performed using the automodel function of the Modeller software package [14, 15] to rapidly generate 272 a single model of the target sequence from each template 273 structure. Modeller uses simulated annealing cycles along 274 with a minimal forcefield and spatial restraints—generally 275 Gaussian interatomic probability densities extracted from 276 the template structure with database-derived statistics de-277 termining the distribution width—to rapidly generate can-278 didate structures of the target sequence from the provided template sequence [14, 15].

While Modeller's automodel function can generate its own alignments automatically, a standalone function was preferable for reasons of programming convenience. As 283 such, we implemented pairwise alignment functionality us-284 ing the the BioPython pairwise2 module [CITE: BioPython]—which uses a dynamic programming algorithm— <sup>286</sup> with the PAM 250 scoring matrix of Gonnet et al. [16]. The alignments are carried out with the align subcommand, prior to the modeling step which is carried out with the build\_models subcommand. The align subcommand also writes a list of the sequence identities for each template to a text file, and this can be used to select models from <sup>292</sup> a desired range of sequence identities. The build\_models <sup>293</sup> subcommand and all subsequent pipeline functions have a --template\_segid\_cutoff flag which can be used to se-295 lect only models with sequence identities greater than the 296 given value.

Models are output as PDB-format coordinate files. To 298 minimize file storage requirements, Ensembler uses the Python gzip library to apply compression to all sizeable text files from the modeling stage onwards. The restraints used 301 by Modeller could potentially be used in alternative addi-302 tional refinement schemes, and **Ensembler** thus provides 303 a flag (--write\_modeller\_restraints\_file) for option-304 ally saving these restraints to file. This option is turned off by  $_{305}$  default, as the restraint files are relatively large (e.g.  $\sim$ 400 KB per model for protein kinase domain targets), and are 307 not expected to be used by the majority of users.

### Filtering of nearly identical models

Because **Ensembler** treats individual chains from source

313 reason, and also to allow users to select for high diversity if 365 with particularly long, extended loops—such as those aris-323 per cluster.

#### **Refinement of models**

324

352

This stage entails the use of molecular dynamics simulations to refine the models built in the previous step. This helps to improve model quality and also prepares models for subsequent production simulation, including solvation with explicit water molecules, if desired.

## Other features

## Tracking provenance information

To aid the user in tracking the provenance of each model, each pipeline function also outputs a metadata file, which helps to link data to the software version used to generate it (both **Ensembler** and its dependencies), and also provides timing and performance information, and other data such 403 as hostname.

#### Rapidly modeling a single template

For users interested in simply using **Ensembler** to rapidly tions. The solvation step solvates each model for a given tar- 406 generate a set of models for a single template sequence, Enget with the same number of waters to facilitate the integra-  $_{\scriptscriptstyle 407}$   ${f sembler}$  provides a command-line tool <code>quickmodel</code>, which tion of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations, such as the construction of data from multiple simulations. tion of MSMs. The target number of waters is selected by first 409 number of templates. For larger numbers of models (such as solvating each model with a specified padding distance (de-40 entire protein families), modeling time is greatly reduced by <sub>364</sub> tion (default: 68th percentile). This helps to prevent models <sub>412</sub> MPI, distributing computation across each model (or across each template, in the case of the loop reconstruction code), and scaling (in a "pleasantly parallel" manner) up to the number of models generated.

## Modeling of all human tyrosine kinase catalytic domains

As a first application of **Ensembler**, we have built models for all 90 human tyrosine kinase (TK) domains listed in UniProt. [JDC: Is there a complete list of these somewhere? Maybe reference supplementary data?] TKs (and protein kinases in general) play important roles in many cellular processes and are involved in a number of types of cancer. [JDC: CITE For example, mutations of Src are associated with colon, breast, and prostate cancer [CITE: Src cancer involvenent], while a translocation between the TK Abl1 and the pseudokinase Bcr is closely associated with chronic myelogenous leukemia [CITE: Abl1 cancer involvement]. Protein kinase domains are thought to have multiple accessible metastable conformation states, and much effort is directed at developing kinase inhibitor drugs which bind to and stabilize inactive conformations [25]. Kinases are thus a particularly interesting subject for study with MSM methods [CITE: recent kinase MSM papers], and this approach stands to benefit greatly from the ability to exploit the full body of available genomic and structural data within the kinase family, e.g. by generating large numbers of starting configurations to be used in highly parallel MD simulation.

We selected all available structures of protein kinase domains (of any species) as templates, for a total of 4433 rived from 3028 individual PDB entries and encompassed 23 different species, with 3634 template structures from human kinase constructs. [JDC: Shouldn't we state which options we used and what Uniprot searches we used for templates and targets? How would someone reproduce what 469 we did here? Can we communicate this beyond just saying 470 'here are the scripts"?]

# **Evaluation of model quality and utility**

All tyrosine kinases

# [JDC: DIscuss Fig. 3 first.]

495

498

To evaluate the diversity of conformations captured for each target sequence, we first computed the RMSD distributions for all models for each target (relative to the model derived from the highest-identity template) are shown in Fig. 4. To better understand the influence of sequence identity on the conformational similarities of resulting models, the sequence identities were stratified based on the sequence identity distribution plotted in Fig. 3, which suggests an intuitive division into three categories, with 307,753 models in the 0-35% sequence identity range, 69,922 models in the 533 35–55% range, and 4893 models in the 55–100% range. It 534 generated, we have analyzed two example TKs (Src and Abl1) clear that higher sequence identity templates result in 535 models with lower RMSDs, while templates with remote se- 536 have been the subject of numerous studies, encompassing quence identities result in larger RMSDs on average.

of analyses can we do for all the TKs? There is so much data 539 or without ligands such as nucleotide substrate or inhibitor 514 here! There must be something neat we can do to examine 540 drugs), showing the kinases in a number of different confor-515 it, right?]

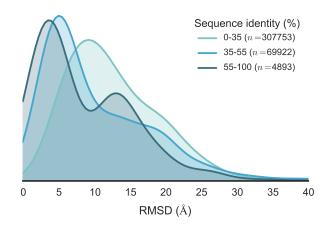

FIG. 4. Distribution of RMSDs to all TK catalytic domain models relative to the model derived from the highest sequence identity template. Distributions are built from data from all 90 TK targets. To better illustrate how conformational similarity depends on sequence identity, these were separated into three sequence identity classes: high identity (55-100%), moderate identity (35-55%), and remote identity (0-35%). The plotted distributions have been smoothed using kernel density estimation. [JDC: Are these computed for the templates or the resulting models?] [DLP: Models.] [JDC: Can we also show the overall distribution without stratification (e.g. in grey in a separate panel)?]

We also analyzed the potential energies of the models at the end of the implicit solvent MD refinement stage. These ranged from -14180 kT to -3590 kT, with a median of -9533 kT and a standard deviation of 1058 kT. The distributions—stratified using the same sequence identity ranges as above—are plotted in Fig. 5, indicating that higher sequence identity templates tend to result in slightly lower energy models. Of the 25,457 models which failed to complete the implicit refinement MD stage, all except 9 failed within the first 1 ps of simulation.

[DLP: for further analysis, a good option might be to try to make a more rigorous assessment of model quality via comparison to reference crystal structures, based on features such as RMSD, phi/psi angles, H-bonds etc. We could also 530 try using the Rosetta heuristic scoring function for this pur-531 pose.]

# Src and Abl1

To provide a more complete evaluation of the models in detail. Due to their importance in cancer, these kinases many different methodologies. These two kinases are thus also interesting targets

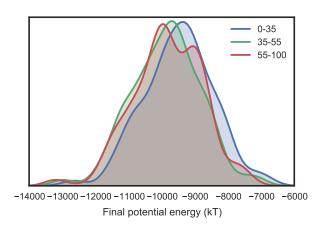

FIG. 5. Distribution of final energies from implicit solvent MD refinement of TK catalytic domain models. To illustrate how the energies are affected by sequence identity, the models are separated into three sequence identity classes: high identity (55–100%). moderate identity (35-55%), and remote identity (0-35%). The plotted distributions have been smoothed using kernel density estimation.

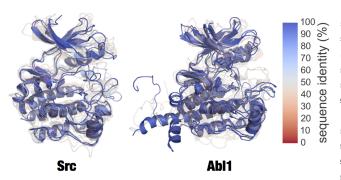

FIG. 6. Superposition of clustered models of Src and Abl1. Superposed renderings of nine models each for Src and Abl1, giving some indication the diversity of conformations generated by Ensembler. The models for each target were divided into three sequence identity ranges (as in Fig. 4), and RMSD-based k-medoids clustering was performed to select three clusters from each. The models shown are the centroids of each cluster. Models are colored and given transparency based on their sequence identity, so that high sequence identity models are blue and opaque, while lower 573 metastable states. Conversely, the lower sequence identity sequence identity models are transparent and red.

542 for MSM studies, with one recent study focusing on mod-543 eling the states which constitute the activation pathway of 578 published structural biology literature on functionally rele-

done either here or in figure caption.] Each model is col- 586 porting Information S1. ored and given a transparency based on the sequence iden-

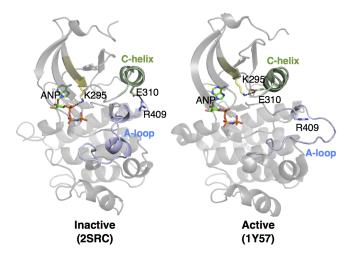

FIG. 7. Two structures of Src, indicating certain residues involved in activation. In the inactive state, E310 forms a salt bridge with R409. During activation, the  $\alpha$ C-helix (green) moves and rotates, orienting E310 towards the ATP-binding site and allowing it to instead form a salt bridge with K295. This positions K295 in the appropriate position for catalysis.

els. High sequence identity models (in opaque blue) tend to 556 be quite structurally similar, with some variation in loops or 557 changes in domain orientation.

The Abl1 renderings in Fig. 6 indicate one high sequence 559 identity model with a long unstructured region at one of the termini, which was unresolved in the original template 561 structure. While such models are not necessarily incorrect or undesirable, it is important to be aware of the effects they may have on production simulations performed under periodic boundary conditions, as long unstructured termini can be prone to interact with a protein's periodic image. Lower sequence identity models (in transparent white or red) indicate much greater variation in all parts of the structure. We believe the mix of high and low sequence identity models to be particularly useful for methods such as MSM building, which require thorough sampling of the conformational landscape. The high sequence identity models could be considered to be the most likely to accurately represent true models could be expected to help push a simulation into re-575 gions of conformation space which might take intractably long to reach if starting a single metastable conformation.

To evaluate the models of Src and Abl1 in the context of the vant conformations, we have focused on two residue pair Fig. 6 shows a superposition of a set of representative 580 distances thought to be important for the regulation of promodels of Src and Abl1. Models were first stratified into three set tein kinase domain activity. We use the residue numbering ranges, based on the structure of the sequence identity dis- 582 schemes for chicken Src (which is commonly used in the littribution (Fig. 3), then subjected to k-medoids clustering sau erature even in reference to human Src)[CITE: 2SRC, 1Y57] to pick three representative models from each sequence 584 and human Abl1 isoform A[CITE: 2F4J, 2HYY, 2G1T] respecidentity range. [JDC: Explain how k-medoids clustering was 585 tively; the exact numbering schemes are provided in Sup-

Fig. 7 shows two structures of Src believed to represent intity between the target and template sequence. The figure 588 active (PDB code: 2SRC) [CITE: 2SRC] and active (PDB code: gives an idea of the variance present in the generated mod- 589 1Y57) [CITE: 1Y57] states. One notable feature which distin-

interaction of E310 from R409 (in the inactive state) to K295 (in the active state), brought about by a rotation of the  $\alpha$ Chelix. These three residues are also well conserved [CITE Kannan Neuwald JMB 2005], and a number of experimental and simulation studies have suggested that this electrostatic switching process plays a role in a regulatory mechanism shared across the protein kinase family [26] [CITE Foda Shan Seeliger Src Nat Commun 2015; Ozkirimli Post Prot Sci 2008]. As such, we have projected the **Ensembler** models for Src and Abl1 onto a space consisting of the distances between these two residue pairs (Fig. 8). The models show strong coverage of regions in which either of the electrostatic interactions is formed, as well as a wide range of regions inbetween. We thus expect that such a set of models, if used as starting configurations for highly parallel MD simu-606 lation, could greatly aid in sampling of functionally relevant 607 conformational states.

### **AVAILABILITY AND FUTURE DIRECTIONS**

#### **Availability**

The code for **Ensembler** is hosted on the collaborative open source software development platform GitHub, 612 http://github.com/choderalab/ensembler The latest release of **Ensembler** can be installed via the conda package manager for Python [http: //conda.pydata.org|:

616 # conda config -add channels https://conda.binstar.org/omnia

618 # conda ensembler

609

627

This will install all dependencies except for Modeller and Rosetta, which are not available through the conda package manager, and thus must be installed separately by the user. The latest source can be downloaded from the GitHub repository, which also contains up-to-date instructions for building and installing the code. [JDC: Where does documentation reside? And example inputs for generating the results in this paper?]

# **Future Directions**

e.g. ATP) yet. We don't handle post-translational modificatant first step toward enabling superfamily- and genomics- 693 tion of such functionality. scale modeling, but there's a lot of work yet to be done.

can be approached in a number of different ways, with vary- especially long residue insertions or deletions. For example, ing degrees of complexity, and there are a number of obvi-

guishes the two structures is the transfer of an electrostatic 640 ous additions and improvements which we plan to implement in future versions of **Ensembler**.

> Some amino acids can exist in different protonation states, depending on pH and on their local environment. These protonation states can have important effects on biological processes. For example, long timescale MD simu-646 lations have suggested that the conformation of the DFG motif of the TK Abl1—believed to be an important regulatory mechanism[CITE: Abl1 DFG flip evidence]—is controlled 649 by protonation of the aspartate [CITE: Shan Shaw Proton-650 dependent switch Abl1 PNAS 2009]. Currently, protonation states are assigned simply based on pH (a user-controllable parameter). At neutral pH, histidines have two protonation states which are approximately equally likely, and in this situation the selection is therefore made based on which state results in a better hydrogen bond. It would be highly de-656 sirable to instead use a method which assigns amino acid 657 protonation states based on a rigorous assessment of the local environment. We thus plan to implement an interface and command-line function for assigning protonation states with MCCE2 [27-29], which uses electrostatics calculations combined with Monte Carlo sampling of side chain conformers to calculate pKa values. [JDC: I think we may want to consider doing that at this stage. Let's discuss.]

Many proteins require the presence of various types of non-protein atoms and molecules for proper function, such as metal ions (e.g.  $Mg^{+2}$ ), cofactors (e.g. ATP) or posttranslational modifications (e.g. phosphorylation, methylation, glycosylation, etc.), and we thus plan for Ensembler to eventually have the capability to include such entities 670 in the generated models. Binding sites for metal ions are 671 frequently found in proteins, often playing a role in catalysis. For example, protein kinase domains contain two binding sites for divalent metal cations, and display significantly increased activity in the presence of  $Mg^{2+}$  [CITE: Adams Taylor Protein Sci 1993], the divalent cation with highest 676 concentration in mammalian cells. Metal ions are often 677 not resolved in experimental structures of proteins, but by 678 taking into account the full range of available structural 679 data, it should be possible in many cases to include metal ions based on the structures of homologous proteins. We are careful to point out, however, that metal ion parame-682 ters in classical MD force fields have significant limitations, particularly in their interactions with proteins [CITE: Sousa Ramos chapter 11 of Kinetics and Dynamics: From Nano- to <sup>685</sup> Bio-Scale, Springer, 2010]. Cofactors and post-translational [JDC: In the Discussion, let's be sure to talk about the lim- 666 modifications are also often not fully resolved in experiitations and what could be improved or added in the future. 687 mental structures, and endogenous cofactors are frequently For example, we don't yet handle counterions (e.g. struc- substituted with other molecules to facilitate experimental tural Zn<sup>2+</sup>), prosthetic groups (e.g. heme), or cofactors structural analysis. Again, **Ensembler** could exploit structural data from a set of homologous proteins to model in ions either (such as phosphorylation, methylation, glycosy- 🚳 these molecules, although there will be likely be a number lation, etc.). It's a good idea to suggest that this is an impor- 692 of challenges to overcome in the design and implementa-

Another limitation with the present version of **Ensembler** Comparative protein modeling and MD simulation set-up 695 involves the treatment of members of a protein family with

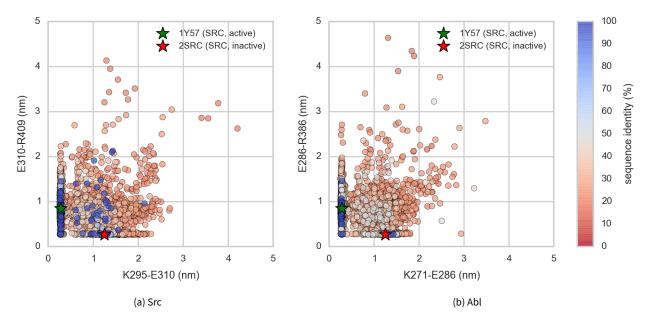

FIG. 8. Src and Abl1 models projected onto the distances between two conserved residue pairs, colored by sequence identity. Two Src structures (PDB entries 1Y57 [CITE] and 2SRC [CITE]) are projected onto the plots for reference, representing active and inactive states respectively. These structures and the residue pairs analyzed here are depicted in Fig. 7. Distances are measured between the center of masses of the three terminal sidechain heavy atoms of each residue. The atom names for these atoms, according to the PDB coordinate files for both reference structures, are—Lys: NZ, CD, CE (ethylamine); Glu: OE1, CD, OE2 (carboxylate); Arg: NH1, CZ, NH2 (part of guanidine).

<sub>698</sub> have a median length of 265 residues and a standard de-<sub>75</sub> tion for a wide range of potential uses by the wider scientific viation of 45, yet the minimum and maximum lengths are 716 community. 102 and 801 respectively. The latter value corresponds to the protein kinase domain of serine/threonine-kinase greatwall, which includes a long insertion between the two main lobes of the catalytic domain. In principle, such insertions could be excluded from the generated models, though a number of questions would arise as to how best to approach this. 706
