The rapidly expanding body of available genomic and protein structural data provides a rich resource for understanding protein dynamics with biomolecular simulation. While computational infrastructure has grown rapidly, simulations on an omics scale are not yet widespread, primarily because software infrastructure to enable simulations at this scale has not kept pace. It should now be possible to study protein dynamics across entire (super)families, exploiting both available structural biology data and conformational similarities across homologous proteins. Here, we present a new tool for enabling high-throughput simulation in the genomics era. Ensembler takes any set of sequences—from a single sequence to an entire superfamily and shepherds them through various stages of modeling and refinement to produce simulation-ready structures. This includes comparative modeling to all relevant PDB structures (which may span multiple conformational states of interest), reconstruction of missing loops, addition of missing atoms, culling of nearly identical structures, assignment of appropriate protonation states, solvation in explicit solvent, and refinement and filtering with molecular simulation to ensure stable simulation. The output of this pipeline is an ensemble of structures ready for subsequent molecular simulations using computer clusters, supercomputers, or distributed computing projects like Folding@home. Ensembler thus automates much of the timeconsuming process of preparing protein models suitable for simulation, while allowing scalability up to entire superfamilies. A particular advantage of this approach can be found in the construction of kinetic models of conformational dynamics—such as Markov state models (MSMs)—which benefit from a diverse array of initial configurations that span the accessible conformational states to aid sampling. We demonstrate the power of this approach by constructing models for all catalytic domains in the human tyrosine kinase family, using all available kinase catalytic domain structures from any organism as structural templates.

Ensembler is free and open source software licensed under the GNU General Public License (GPL) v2. It should run on all major operating systems, and has been tested on Linux and OS X. The latest release can be installed via the conda package manager, and the latest source can be downloaded from https://github.com/choderalab/ensembler.

Keywords: molecular dynamics simulation; comparative modeling; distributed simulation

I. INTRODUCTION

Recent advances in genomics and structural biology have helped generate an enormous wealth of protein data at the level of amino-acid sequence and three-dimensional structure. However, proteins typically exist as an ensemble of thermally accessible conformational states, and static structures provide only a snapshot of their rich dynamical behavior. Many functional properties—such as the ability to bind small molecules or interact with signaling partners—require transitions between states, encompassing anything from reorganization of sidechains at binding interfaces to domain motions to large scale folding-unfolding events. Drug discovery could also benefit from a more extensive consideration of protein dynamics, whereby small molecules might be selected based on their predicted ability to bind and trap a protein target in an inactive state [1].

Molecular dynamics (MD) simulations have the capabilMolecular dynamics (MD) simulations have the capabilJity, in principle, to describe the time evolution of a protein in atomistic detail, and have proven themselves to be a useful tool in the study of protein dynamics. A number of mature software packages and forcefields are now available, and much recent progress has been driven by advances in computing architecture. For example, many MD

29 packages are now able to exploit GPUs [2, 3], which pro-30 vide greatly improved simulation efficiency per unit cost rel-31 ative to CPUs, while distributed computing platforms such 32 as Folding@home [4], Copernicus [5], and GPUGrid [6], al-33 low scalability on an unprecedented level. In parallel, meth-34 ods for building human-understandable models of protein 35 dynamics from noisy simulation data, such as Markov state modeling (MSM) approaches, are now reaching maturity [7– ³⁷ 9]. MSM methods in particular have the advantage of be-38 ing able to aggregate data from multiple independent MD 39 trajectories, facilitating parallelization of production simu-40 lations and thus greatly alleviating overall computational 41 cost. There also exist a number of mature software packages 42 for comparative modeling of protein structures, in which a 43 target protein sequence is modeled using one or more struc-44 tures as templates [10, 11].

However, it remains difficult for researchers to exploit the full variety of available protein sequence and structural data in simulation studies, largely due to limitations in software architecture. For example, the set up of a biomolecular simulation is typically performed manually, encompassing a series of fairly standard (yet time-consuming) steps such as the choice of protein sequence construct and starting structure(s), addition of missing residues and atoms, solvation with explicit water and counterions (and potentially buffer components and cosolvents), choice of simulation parameters (or parameterization schemes for components where

^{*} Corresponding author; john.chodera@choderalab.org

minimization, and one or more short preparatory MD simulations to equilibrate the system and relax the simulation cell. Due to the laborious and manual nature of this process, simulation studies typically consider only one or a few proteins and starting configurations. Worse still, studies (or collections of studies) that do consider multiple proteins often suffer from the lack of consistent best practices in this preparation process, making comparisons between related proteins unnecessarily difficult.

The ability to fully exploit the large quantity of available protein sequence and structural data in biomolecular simulation studies could open up many interesting avenues for research, enabling the study of entire protein families or superfamilies within a single organism or across multiple organisms. The similarity between members of a given protein family could be exploited to generate arrays of conformational models, which could be used as starting configurations to aid sampling in MD simulations. This approach would be highly beneficial for many MD methods, such as MSM construction, which require global coverage of the conformational landscape to realize their full potential, and would also be particularly useful in cases where structural data is present for only a subset of the members of a protein family. It would also aid in studying protein families known to have multiple metastable conformations—such as kinases—for which the combined body of structural data for the family may cover a large range of these conformations, while the available structures for any individual member might encompass only one or two distinct conformations.

Here, we present the first steps toward bridging the gap between biomolecular simulation software and omicsscale sequence and structural data: a fully automated open source framework for building simulation-ready protein models in multiple conformational substates scalable from single sequences to entire superfamilies. **Ensembler** provides functions for selecting target sequences and homologous template structures, and (by interfacing with a number of external packages) performs pairwise alignments, comparative modeling of target-template pairs, and several stages of model refinement. As an example application, we have constructed models for the entire set of human tyrosine kinase catalytic domains, using all available structures of protein kinase domains (from any species) as templates. This results in a total of almost 400,000 models, and we demonstrate that these provide wide-ranging coverage of known functionally relevant conformations. By using these models as starting configurations for highly parallel MD simulations, we expect their structural diversity to greatly aid in sampling of conformational space.

We anticipate that the tool will prove to be useful in a 158 number of other ways. For example, the generated models could represent valuable data sets even without subsequent production simulation, allowing exploration of the 🔐 "Protein kinase 2", "Protein kinase; truncated", "Protein kiconformational diversity present within the available struc- 162 nase; inactive", "SH2", "SH3", etc. To select only domains tural data for a given protein family. DESIGN AND IMPLEMENTATION

Ensembler is written in Python, and can be used via a command-line tool (ensembler) or via a flexible Python API 119 to allow integration of its components into other applica-

The **Ensembler** modeling pipeline comprises a series of 122 stages which are performed in a defined order. A visual overview of the pipeline is shown in Fig. 1. The various stages of this pipeline are described in detail below.

Target selection and retrieval

The first stage entails the selection of a set of target protein sequences—the sequences the user is interested in generating simulation-ready structural models for. This may be 129 a single sequence—such as a full-length protein or a con-130 struct representing a single domain—or a collection of sequences, such as a particular domain from an entire family of proteins. The output of this stage is a FASTA-formatted text file containing the desired target sequences with corresponding arbitrary identifiers.

The ensembler command-line tool allows targets to be selected from UniProt—a freely accessible resource for protein sequence and functional data (uniprot.org) [12]— 138 via a UniProt search guery. To retrieve target sequences 139 from UniProt, the subcommand gather_targets us used with the --query flag followed by a UniProt query string conforming to the same syntax as the search 142 function available on the UniProt website. For exam---query 'mnemonic:SRC_HUMAN' would select 143 ple, the full-length human Src sequence, while --query 'domain: "Protein kinase" AND organism: "homo $_{\mbox{\scriptsize 146}}$ sapiens" AND reviewed:yes' would select all human protein kinases which have been reviewed by a human 148 curator. In this way, the user may select a single protein, many proteins, or an entire superfamily from UniProt. 150 The program outputs a FASTA file, setting the UniProt mnemonic (e.g. SRC_HUMAN) as the identifier for each target protein.

In many cases, it will be desirable to build models of an isolated protein domain, rather than the full-length pro-155 tein. The gather_targets subcommand allows protein domains to be selected from UniProt data by passing a regular expression string to the --uniprot_domain_regex flag. For example, the above --query flag for selecting all human protein kinases returns UniProt entries with domain annotations including "Protein kinase", "Protein kinase 1", 113 tunity to make concrete certain "best practices", such as the 165 inactive)'. If the --uniprot_domain_regex flag is

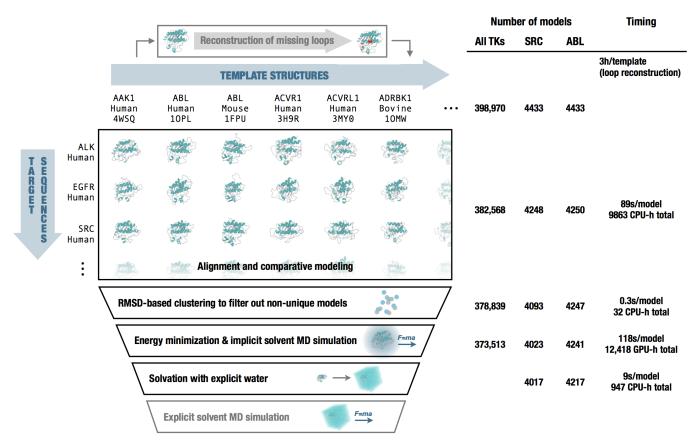

FIG. 1. Diagrammatic representation of the various stages of the Ensembler pipeline and illustrative statistics for modeling all human tyrosine kinase catalytic domains. On the left, the various stages of the Ensembler pipeline are shown. On the right, the number of viable models surviving each stage of the pipeline is shown for modeling all 90 tyrosine kinases (All TKs) and representative individual tyrosine kinases (SRC and ABL). Typical timings on a computer cluster (containing Intel Xeon E5-2665 2.4GHz hyperthreaded processors and NVIDIA GTX-680 or GTX-Titan GPUs) is reported to illustrate resource requirements per model for modeling the entire set of tyrosine kinases. Note that CPU-h denotes the number of hours consumed by the equivalent of a single CPU hyperthread and GPU-h on a single GPU—parallel execution via MPI reduces wall clock time nearly linearly.

166 used, target identifiers are set with the form [UniProt 185 the same protein family as the targets, guaranteeing some mnemonic]_D[domain index], where the latter part repre- 186 degree of homology between targets and templates. sents a 0-based index for the domain—necessary because a 187 est (e.g. JAK1_HUMAN_DO, JAK1_HUMAN_D1).

Target sequences can also be defined manually (or from another program) by providing a FASTA-formatted text file containing the desired target sequences with corresponding arbitrary identifiers.

Template selection and retrieval

175

The ensembler gather_templates subcommand prosingle target protein may contain multiple domains of inter- 188 vides methods for selecting template structures from either UniProt or the PDB (http://www.rcsb.org/pdb), speci-190 fied by the --gather_from flag. Both methods select templates at the level of PDB chains—a PDB structure containing multiple chains with identical sequence spans (e.g. for 193 crystal unit cells with multiple asymmetric units) would thus 194 give rise to multiple template structures.

Selection of templates from the PDB simply requires 196 passing a list of PDB IDs as a comma-separated string, e.g. --query 2H8H, 1Y57. Specific PDB chain IDs can Ensembler uses comparative modeling to build models, 198 optionally also be selected via the --chainids flag. and as such requires a set of structures to be used as tem- 199 The program retrieves structures from the PDB server, plates. The second stage thus entails the selection of tem- 200 as well as associated data from the SIFTS service plates and storage of associated sequences, structures, and 201 (www.ebi.ac.uk/pdbe/docs/sifts) [13], which provides identifiers. These templates can be specified manually, or 202 residue-level mappings between PDB and UniProt entries. using the ensembler gather_templates subcommand to 203 The SIFTS data is used to extract template sequences, automatically select templates based on a search of the 204 retaining only residues which are resolved and match Protein Data Bank (PDB) or UniProt. A recommended ap- 205 the equivalent residue in the UniProt sequence—non-184 proach is to select templates from UniProt which belong to 206 wildtype residues are thus removed from the template

Sequences are stored in a FASTA file, with identifiers of the form [UniProt mnemonic]_D[UniProt domain index]_[PDB ID]_[PDB chain ID], e.g. SRC_HUMAN_DO_2H8H_A. Matching residues exthen tracted from the original coordinate files and stored as PDB-format coordinate files.

Selection of templates from UniProt proceeds in a similar fashion as for target selection; the --query flag is used select full-length proteins from UniProt, while the optional --uniprot_domain_regex flag allows selection of ndividual domains with a regular expression string. The returned UniProt data for each protein includes a list of associated PDB chains and their residue spans, and this information is used to select template structures, using the same method as for template selection from the PDB. Only structures solved by X-ray crystallography or NMR are selected, thus excluding computer-generated models available from the PDB. If the --uniprot_domain_regex flag is used, then templates are truncated at the start and end of the domain sequence.

Templates can also be defined manually. Manual specification of templates simply requires storing the sequences and arbitrary identifiers in a FASTA file, and the structures as PDB-format coordinate files with filenames matching the identifiers in the sequence file. The structure residues must also match those in the sequence file.

220

235

Template refinement

Unresolved template residues can optionally be modeled into template structures with the loopmodel subcommand, which employs a kinematic closure algorithm provided via the loopmodel tool of the Rosetta software suite [14, 15]. Because fewer loops need to be built during the subsequent target model-building stage, we find that prebuilding template loops tends to provide higher-quality models after ompletion of the **Ensembler** pipeline. [JDC: Should we cite ur evidence for this with the TKs, or maybe tone back the claim a bit to say that it is possible this could make things asier?] [DLP: Might be worth investigating an algorithm called pokefind (or knotfind, which I think is an earlier version) which aims to find knots in proteins, of the type which encouraged us to use Rosetta to reconstruct template loops. DOI: 10.1093/bioinformatics/btp198 It sounds like these algorithms have actually been implemented in Rosetta, so this could explain why Rosetta seems to do better at avoiding making these knotted structures. Would be useful to check this out further first, and then decide whether or not to discuss the knotted structures in the manuscript.] 255

structures. Furthermore, PDB chains with less than a 262 model missing residues at the termini of a structure—such

Modeling

In the modeling stage, structural models of the target sequence are generated from the template structures, with the goal of modeling the target in a variety of conformations that could be significantly populated under equilibrium conditions.

Modeling is performed using the automodel function of the Modeller software package [16, 17] to rapidly generate a single model of the target sequence from each template 273 structure. Modeller uses simulated annealing cycles along with a minimal forcefield and spatial restraints—generally Gaussian interatomic probability densities extracted from the template structure with database-derived statistics determining the distribution width—to rapidly generate candidate structures of the target sequence from the provided template sequence [16, 17].

While Modeller's automodel function can generate its own alignments automatically, a standalone function was preferable for reasons of programming convenience. As such, we implemented pairwise alignment functionality using the the BioPython pairwise2 module [18]—which uses 285 a dynamic programming algorithm—with the PAM 250 scoring matrix of Gonnet et al. [19]. The alignments are carried out with the align subcommand, prior to the modeling step which is carried out with the build_models subcommand. The align subcommand also writes a list of the sequence identities for each template to a text file, and this can be used to select models from a desired 292 range of sequence identities. The build_models subcommand and all subsequent pipeline functions have a --template_seqid_cutoff flag which can be used to se-295 lect only models with sequence identities greater than the 296 given value.

Models are output as PDB-format coordinate files. To minimize file storage requirements, Ensembler uses the Python gzip library to apply compression to all sizeable text files from the modeling stage onwards. The restraints used 301 by Modeller could potentially be used in alternative additional refinement schemes, and **Ensembler** thus provides 303 a flag (--write_modeller_restraints_file) for option-³⁰⁴ ally saving these restraints to file. This option is turned off by $_{305}$ default, as the restraint files are relatively large (e.g. \sim 400 306 KB per model for protein kinase domain targets), and are 307 not expected to be used by the majority of users.

Filtering of nearly identical models

Because **Ensembler** treats individual chains from source cally uses the remodeled version of a template if available, 310 PDB structures as individual templates, a number of modbut otherwise falls back to using the non-remodeled ver- 311 els may be generated with very similar structures if these 313 this reason, and also to allow users to select for high di- 368 along with a modified generalized Born solvent model [30] versity if they so choose, **Ensembler** provides a way to fil- 369 as implemented in the OpenMM package [2]. tain only a single model per cluster.

Refinement of models

325

While the utility of comparative modeling methods has 327 been greatly enhanced by the recent explosion in the availability of protein structural data, the structures generated are generally considered "low-resolution" in comparison to those derived using experimental techniques such as X-ray crystallography. RMS errors of \sim 3 Åfor C $_{\alpha}$ atoms relative to a native crystal structure are typical [25-27]. A number of refinement methods have been developed to help steer homology models toward more "native-like" conformations [26, 27], of which MD simulations are an important example. While long-timescale unrestrained MD simulations (on the order of 100 μ s) have been found to be ineffective for recapitulating native-like conformations, possibly due to forcefield issues [25], even relatively short simas sidechain orientation [27].

Solvation and NPT equilibration

While protein-only models may be sufficient for struc-384 tural analysis or implicit solvent simulations, **Ensembler** 385 also provides a stage for solvating models with explicit wa-386 ter and performing a round of explicit-solvent MD refinement/equilibration under isothermal-isobaric (NPT) condi-388 tions. The solvation step solvates each model for a given target with the same number of waters to facilitate the inulations can be useful for relaxing structural elements such 390 tegration of data from multiple simulations, which is impor-391 tant for methods such as the construction of MSMs. The Ensembler thus includes a refinement module, which 392 target number of waters is selected by first solvating each uses short molecular dynamics simulations to refine the 393 model with a specified padding distance (default: 10 Å), models built in the previous step. Packaging

Ensembler provides a packaging module which 419 420 can be used to prepare models for other uses. package_models subcommand currently provides functions (specified via the --package_for flag) for compressing models in preparation for data transfer, or for organizing them with the appropriate directory and file structure for production simulation on the distributed computing platform Folding@home [4]. The module could easily be extended to add methods for preparing models for other purposes. For example, production simulations could alternatively be run using Copernicus [5]—a framework for performing parallel adaptive MD simulations— 431 or GPUGrid [6]—a distributing computing platform which $_{
m 432}$ relies on computational power voluntarily donated by the $_{
m 477}$ ⁴³³ owners of nondedicated GPU-equipped computers.

Rapidly modeling a single template

For users interested in simply using **Ensembler** to rapidly generate a set of models for a single template sequence, Ensembler provides a command-line tool quickmodel, which performs the entire pipeline for a single target with a small number of templates. For larger numbers of models (such as entire protein families), modeling time is greatly reduced by using the main modeling pipeline, which is parallelized via MPI, distributing computation across each model (or across each template, in the case of the loop reconstruction code), 452 and scaling (in a "pleasantly parallel" manner) up to the ₄₅₃ number of models generated.

RESULTS

Modeling of all human tyrosine kinase catalytic domains

As a first application of **Ensembler**, we have built models for the human tyrosine kinase (TK) family. [TODO: Add list of TK UniProt identifiers and gene names, probably in 459 SI.] TKs (and protein kinases in general) play important roles 460 in many cellular processes and are involved in a number 515 correlation between remodeling failures and the number of 461 of types of cancer [34]. For example, mutations of Src are 516 missing residues (Fig. 2, top); templates for which remodel-

462 associated with colon, breast, prostate, lung, and pancreatic cancers [35], while a translocation between the TK Abl1 and the pseudokinase Bcr is closely associated with chronic 465 myelogenous leukemia [36]. Protein kinase domains are thought to have multiple accessible metastable conformation states, and much effort is directed at developing kinase 468 inhibitor drugs which bind to and stabilize inactive conformations [37]. Kinases are thus a particularly interesting sub-470 ject for study with MSM methods [38], and this approach 471 stands to benefit greatly from the ability to exploit the full 472 body of available genomic and structural data within the 473 kinase family, e.g. by generating large numbers of starting 474 configurations to be used in highly parallel MD simulation.

We selected all 90 TK domains annotated in UniProt as 476 targets, using the following command:

gather_targets --query 'family:"tyr protein kinase family" AND

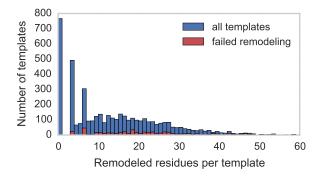

```
478 organism: "homo sapiens" AND reviewed: yes' --uniprot_domain_regex
                                                            479 '^Protein kinase(?!; truncated)(?!; inactive)'
                                                            480 The 'reviewed:yes' expression in the UniProt query
                                                            481 ensured that only UniProt entries which have been re-
                                                            viewed by a human expert were included in the results. The
                                                               --uniprot_domain_regex regular expression resulted

495 target-template pairs. The templates were derived from 3028 individual PDB entries and encompassed 23 different species, with 3634 template structures from human kinase 498 constructs.

Ensembler modeling statistics

Crystallographic structures of kinase catalytic domains 501 generally contain a significant number of missing residues (median 11, standard deviation 13, max 102) due to the high mobility of several loops (Fig. 2, top), with a number of these 504 missing spans being significant in length (median 5, stan-505 dard deviation 6, max 82; Fig. 2, bottom). To reduce the reliance on the Modeller rapid model construction stage to reconstruct very long unresolved loops, unresolved template residues were first remodeled using the loopmodel subcommand. Out of 3666 templates with one or more missing residues, 3134 were successfully remodeled by the 511 Rosetta loop modeling stage (with success defined simply as program termination with out error); most remodeling fail-₅₁₃ ures were attributable to unsatisfiable spatial constraints imposed by the original template structure. There was some

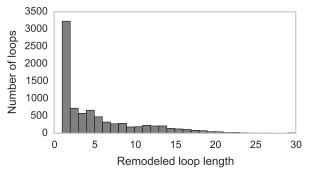

FIG. 2. Distributions for the number of missing residues in the **TK templates.** The upper histograms show the number of missing residues per template, for all templates (blue) and for only those templates for which template remodeling with the loopmodel 543 files, which are about 397 kB per model) and 77 kB for the subcommand failed (red). The lower histogram shows the number 544 of residues in each missing loop, for all templates.

ing failed had a median of 20 missing residues, compared to a median of 14 missing residues for templates for which remodeling was successful.

Following loop remodeling, the **Ensembler** pipeline was performed up to and including the implicit solvent MD re- 547 finement stage, which completed with 373.513 (94%) sur- 548 relative to each target sequence, we calculated sequence viving models across all TKs. To obtain statistics for the sol- 549 identity distributions, as shown in Fig. 3. This suggests an ration stage without generating a sizeable amount of coordinate data (with solvated PDB coordinate files taking up ssi els in the 0-35% sequence identity range, 69,922 models in about 0.9 MB each), the solvate subcommand was per- 552 the 35-55% range, and 4893 models in the 55-100% range. formed for two representative individual kinases (Src and 553 We then computed the RMSD distributions for the models Abl1). 528

shown in Fig. 1, indicating that the greatest attrition oc- 556 sess the diversity of conformations captured by the modcurred during the modeling stage. The number of re- 557 eling pipeline. Furthermore, to understand the influence fined models for each target ranged from 4005 to 4248, 558 of sequence identity on the conformational similarities of with a median of 4160 and standard deviation of 60. 559 the resulting models, the RMSD distributions were strati-Fig. 1 also indicates the typical timing achieved on a clus- 560 fied based on the three sequence identity categories deter for each stage, showing that the build_models and sell scribed above. This analysis indicates that higher sequence refine_implicit_md stages are by far the most compute- 562 identity templates result in models with lower RMSDs, while intensive.

Each model generated about 116 KB of file data (up to 564 RMSDs on average. and including the implicit solvent MD refinement stage), totalling 0.5 GB per TK target or 41 GB for all 90 TKs. The data 566 at the end of the implicit solvent MD refinement stage. generated per model breaks down as 39 kB for the output 557 These ranged from -14180 kT to -3590 kT, with a median 542 from the modeling stage (without saving Modeller restraints 568 of -9533 kT and a standard deviation of 1058 kT. The

537

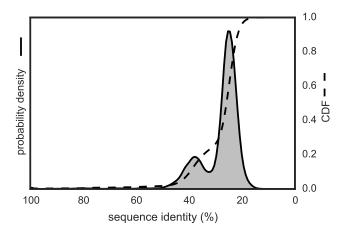

FIG. 3. Template-target sequence identity distribution for human tyrosine kinase catalytic domains. Sequence identities are calculated from all pairwise target-template alignments, where targets are human kinase catalytic domain sequences and templates are all kinase catalytic domains from any organism with structures in the PDB, as described in the text. A kernel density estimate of the target-template sequence identity probability density function is shown as a solid line with shaded region, while the corresponding cumulative distribution function is shown as a dashed line.

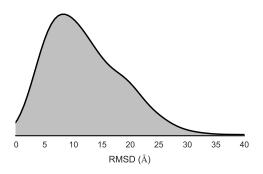

implicit solvent MD refinement stage.

Evaluation of model quality and utility

All tyrosine kinases

To evaluate the variety of template sequence similarities intuitive division into three categories, with 307,753 mod-554 created for each target (relative to the model derived from The number of models which survived each stage are 555 the template with highest sequence identity) Fig. 4, to as-563 templates with remote sequence identities result in larger

We also analyzed the potential energies of the models

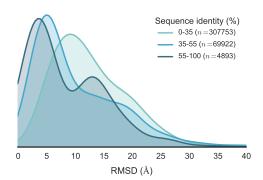

FIG. 4. Distribution of RMSDs to all TK catalytic domain models relative to the model derived from the highest sequence identity template. Distributions are built from data from all 90 TK targets. To better illustrate how conformational similarity depends on sequence identity, the lower plot illustrates the distributions as stratified into three sequence identity classes: high identity (55-100%), moderate identity (35–55%), and remote identity (0–35%). The plotted distributions have been smoothed using kernel density estimation.

569 distributions—stratified using the same sequence identity ranges as above—are plotted in Fig. 5, indicating that higher sequence identity templates tend to result in slightly lower energy models. Of the 25,457 models which failed to complete the implicit refinement MD stage, all except 9 failed within the first 1 ps of simulation.

Src and Abl1

drugs), showing the kinases in a number of different confor- 596 tity between the target and template sequence. The figure mations. These two kinases are thus also interesting targets syr gives an idea of the variance present in the generated mod-585 for MSM studies, with one recent study focusing on mod-598 els. High sequence identity models (in opaque blue) tend to

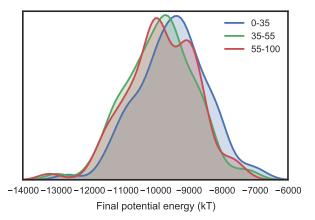

FIG. 5. Distribution of final energies from implicit solvent MD refinement of TK catalytic domain models. To illustrate how the energies are affected by sequence identity, the models are separated into three sequence identity classes: high identity (55–100%). moderate identity (35-55%), and remote identity (0-35%). The plotted distributions have been smoothed using kernel density estimation.

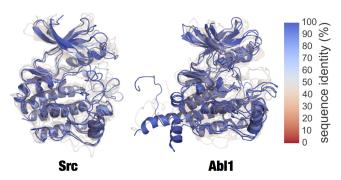

FIG. 6. Superposition of clustered models of Src and Abl1. Superposed renderings of nine models each for Src and Abl1, giving some indication the diversity of conformations generated by Ensembler. The models for each target were divided into three sequence identity ranges (as in Fig. 4), and RMSD-based k-medoids clustering was performed to select three clusters from each. The models shown are the centroids of each cluster. Models are colored and given transparency based on their sequence identity, so that high sequence identity models are blue and opaque, while lower sequence identity models are transparent and red.

587 Src [38].

Fig. 6 shows a superposition of a set of representative To provide a more complete evaluation of the models 589 models of Src and Abl1. Models were first stratified into three generated, we have analyzed two example TKs (Src and Abl1) 590 ranges, based on the structure of the sequence identity disin detail. Due to their importance in cancer, these kinases $_{591}$ tribution (Fig. 3), then subjected to k-medoids clustering have been the subject of numerous studies, encompassing 592 to pick three representative models from each sequence many different methodologies. In terms of structural data, 593 identity range. [JDC: Explain how k-medoids clustering was a large number of crystal structures have been solved (with 594 done either here or in figure caption.) Each model is color without ligands such as nucleotide substrate or inhibitor 595 ored and given a transparency based on the sequence iden-586 eling the states which constitute the activation pathway of 599 be quite structurally similar, with some variation in loops or

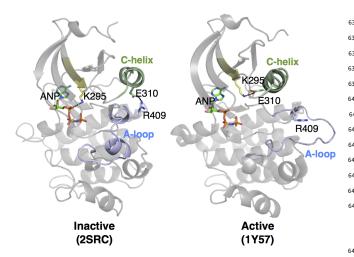

FIG. 7. Two structures of Src, indicating certain residues in**volved in activation.** In the inactive state, E310 forms a salt bridge with R409. During activation, the α C-helix (green) moves and rotates, orienting E310 towards the ATP-binding site and allowing it to instead form a salt bridge with K295. This positions K295 in the appropriate position for catalysis.

600 changes in domain orientation.

The Abl1 renderings in Fig. 6 indicate one high sequence 655 pydata.org]: 602 identity model with a long unstructured region at one of 656 conda config -add channels https://conda.binstar.org/omnia the termini, which was unresolved in the original template 657 conda ensembler structure. While such models are not necessarily incorrect 658 We believe the mix of high and low sequence identity mod- 665 results in this paper? Put this in the TK model data set?] els to be particularly useful for methods such as MSM building, which require thorough sampling of the conformational landscape. The high sequence identity models could be 666 considered to be the most likely to accurately represent true metastable states. Conversely, the lower sequence identity 667 long to reach if starting a single metastable conformation.

To evaluate the models of *Src* and *Abl1* in the context of the 671 ment in future versions of **Ensembler**. published structural biology literature on functionally releing schemes are provided in Supporting Information S1.

tion of E310 from R409 (in the inactive state) to K295 (in the 684 results in a better hydrogen bond. It would be highly de- $_{634}$ active state), brought about by a rotation of the α C-helix. $_{685}$ sirable to instead use a method which assigns amino acid

635 These three residues are also well conserved [44], and a number of experimental and simulation studies have suggested that this electrostatic switching process plays a role in a regulatory mechanism shared across the protein kinase family [38, 45, 46]. As such, we have projected the Ensem**bler** models for Src and Abl1 onto a space consisting of the distances between these two residue pairs (Fig. 8). The models show strong coverage of regions in which either of the electrostatic interactions is formed, as well as a wide range of regions inbetween. We thus expect that such a set of models, if used as starting configurations for highly parallel MD simulation, could greatly aid in sampling of functionally relevant conformational states.

AVAILABILITY AND FUTURE DIRECTIONS

Availability

The code for **Ensembler** is hosted on the collaborative open source software development platform GitHub, 652 http://github.com/choderalab/ensembler

653 The latest release of **Ensembler** can be installed via the conda package manager for Python [http://conda.

This will install all dependencies except for Modeller and or undesirable, it is important to be aware of the effects they 659 Rosetta, which are not available through the conda packmay have on production simulations performed under peri- on age manager, and thus must be installed separately by the odic boundary conditions, as long unstructured termini can 🔞 user. The latest source can be downloaded from the GitHub be prone to interact with a protein's periodic image. Lower 662 repository, which also contains up-to-date instructions for sequence identity models (in transparent white or red) in- 663 building and installing the code. [TODO: Add link to docudicate much greater variation in all parts of the structure. 664 mentation. What about example inputs for generating the

Future Directions

Comparative protein modeling and MD simulation set-up models could be expected to help push a simulation into re- 668 can be approached in a number of different ways, with varygions of conformation space which might take intractably 669 ing degrees of complexity, and there are a number of obvious additions and improvements which we plan to imple-

Some amino acids can exist in different protonation vant conformations, we have focused on two residue pair 673 states, depending on pH and on their local environment. distances thought to be important for the regulation of pro- 674 These protonation states can have important effects on bitein kinase domain activity. We use the residue number- 675 ological processes. For example, long timescale MD simuing schemes for chicken Src (which is commonly used in the 676 lations have suggested that the conformation of the DFG iterature even in reference to human Src) [39, 40] and hu- 677 motif of the TK Abl1—believed to be an important regulaman Abl1 isoform A [41–43] respectively; the exact number- 678 tory mechanism [CITE: Abl1 DFG flip evidence]—is controlled by protonation of the aspartate [47]. Currently, protonation Fig. 7 shows two structures of Src believed to repre- 680 states are assigned simply based on pH (a user-controllable sent inactive (PDB code: 2SRC) [39] and active (PDB code: 681 parameter). At neutral pH, histidines have two protonation 1Y57) [40] states. One notable feature which distinguishes 682 states which are approximately equally likely, and in this sitthe two structures is the transfer of an electrostatic interac- 683 uation the selection is therefore made based on which state

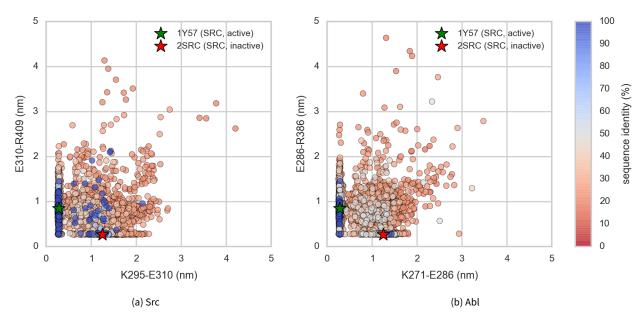

FIG. 8. Src and Abl1 models projected onto the distances between two conserved residue pairs, colored by sequence identity. Two Src structures (PDB entries 1Y57 [40] and 2SRC [39]) are projected onto the plots for reference, representing active and inactive states respectively. These structures and the residue pairs analyzed here are depicted in Fig. 7. Distances are measured between the center of masses of the three terminal sidechain heavy atoms of each residue. The atom names for these atoms, according to the PDB coordinate files for both reference structures, are—Lys: NZ, CD, CE (ethylamine); Glu: OE1, CD, OE2 (carboxylate); Arg: NH1, CZ, NH2 (part of guanidine).

protonation states based on a rigorous assessment of the η_6 a set of homologous proteins to model in these molecules, states with MCCE2 [48–50], which uses electrostatics calcu- 719 tionality. lations combined with Monte Carlo sampling of side chain 720 conformers to calculate pKa values.

Many proteins require the presence of various types of non-protein atoms and molecules for proper function, such as metal ions (e.g. Mg⁺²), cofactors (e.g. ATP) or posttranslational modifications (e.g. phosphorylation, methylaion, glycosylation, etc.), and we thus plan for Ensembler to eventually have the capability to include such entities in the generated models. Binding sites for metal ions are frequently found in proteins, often playing a role in catalysis. For example, protein kinase domains contain two binding sites for divalent metal cations, and display significantly increased activity in the presence of Mg^{2+} [51], the divalent cation with highest concentration in mammalian cells. Metal ions are often not resolved in experimental structures of proteins, but by taking into account the full range of available structural data, it should be possible in many cases to include metal ions based on the structures of homolo- 734 715 ysis. Again, **Ensembler** could exploit structural data from 742 community.

local environment. We thus plan to implement an inter- m although there will be likely be a number of challenges to face and command-line function for assigning protonation 78 overcome in the design and implementation of such func-

> Another limitation with the present version of **Ensembler** involves the treatment of members of a protein family with ⁷²² especially long residue insertions or deletions. For example, 123 the set of all human protein kinase domains listed in UniProt ₇₂₄ have a median length of 265 residues and a standard deviation of 45, yet the minimum and maximum lengths are 102 and 801 respectively. The latter value corresponds to the protein kinase domain of serine/threonine-kinase greatwall, which includes a long insertion between the two main 129 lobes of the catalytic domain. In principle, such insertions 730 could be excluded from the generated models, though a ₇₃₁ number of questions would arise as to how best to approach

Conclusion

We believe **Ensembler** to be an important first step togous proteins. We are careful to point out, however, that $_{735}$ ward enabling computational modeling and simulation of metal ion parameters in classical MD force fields have signif- 736 proteins on the scale of entire protein families, and suggest cant limitations, particularly in their interactions with pro- 737 that it could likely prove useful for tasks beyond its original teins [52]. Cofactors and post-translational modifications 738 aim of providing diverse starting configurations for MD simare also often not fully resolved in experimental structures, 739 ulations. The code is open source and has been developed and endogenous cofactors are frequently substituted with 740 with extensibility in mind, in order to facilitate its customizaother molecules to facilitate experimental structural anal- 741 tion for a wide range of potential uses by the wider scientific
