The rapidly expanding body of available genomic and protein structural data provides a rich resource for understanding protein dynamics with biomolecular simulation. While computational infrastructure has grown rapidly, simulations on an omics scale are not yet widespread, primarily because software infrastructure to enable simulations at this scale have not kept pace. It should now be possible to study protein dynamics across entire (super)families, exploiting both available structural biology data and conformational similarities across homologous proteins. Here, we present a new tool for enabling high-throughput simulation in the genomics era. Ensembler takes any set of sequences—from a single sequence to an entire superfamily and shepherds them through various stages of modeling and refinement to produce simulation-ready structures. This includes comparative modeling to all relevant PDB structures (which may span multiple conformational states of interest), reconstruction of missing loops, addition of missing atoms, culling of nearly identical structures, assignment of appropriate protonation states, solvation in explicit solvent, and refinement and filtering with molecular simulation to ensure stable simulation. The output of this pipeline is an ensemble of structures ready for subsequent molecular simulations using computer clusters, supercomputers, or distributed computing projects like Folding@home. **Ensembler** automates much of the time-consuming process of preparing protein models suitable for simulation, while allowing scalability up to entire superfamilies. [JDC: Prior sentence is redundant?] A particular advantage of this approach can be found in the construction of kinetic models of conformational dynamics—such as Markov state models—which benefit from a diverse array of initial configurations that span the accessible conformational states to aid sampling. We demonstrate the power of this approach by constructing models for all catalytic domains in the human tyrosine kinase family, using all available kinase catalytic domain structures from any organism as structural templates.

Ensembler is free and open source software licensed under the GNU General Public License (GPL) v2. It should run on all major operating systems, and has been tested on Linux and OS X. The latest release can be installed via the conda package manager, and the latest source can be downloaded from https://github.com/choderalab/ensembler.

Keywords: molecular dynamics simulation; comparative modeling; distributed simulation

I. INTRODUCTION

Recent advances in genomics and structural biology have helped generate an enormous wealth of protein data at the level of amino-acid sequence and three-dimensional structure. However, proteins typically exist as an ensemble of thermally accessible conformational states, and static structures provide only a snapshot of their rich dynamical behavior. Many functional properties—such as the ability to bind small molecules or interact with signaling partners—require transitions between states, encompassing anything from reorganization of sidechains at binding interfaces to domain motions to large scale folding-unfolding events. Drug discovery could also benefit from a more extensive consideration of protein dynamics, whereby small molecules might be selected based on their predicted ability to bind and trap a protein target in an inactive state [1].

Molecular dynamics (MD) simulations have the capability, in principle, to describe the time evolution of a protein in atomistic detail, and have proven themselves to be a useful tool in the study of protein dynamics. A number of mature software packages and forcefields are available, and

27 much recent progress has been driven by advances in com-28 puting architecture. For example, many MD packages are 29 now able to exploit GPUs, which provide greatly improved 30 simulation efficiency per unit cost relative to CPUs, while 31 distributed computing platforms such as Folding@home 32 [CITE], GPUGrid [CITE], and Copernicus [CITE] allow scala-33 bility on an unprecedented level. In parallel, methods for 34 building human-understandable models of protein dynam-35 ics from noisy simulation data, such as Markov state mod-36 eling (MSM) approaches, are now reaching maturity [CITE 37 MSM reviews]. MSM methods in particular have the advan-38 tage of being able to aggregate data from multiple indepen-39 dent MD trajectories, facilitating parallelization of produc-40 tion simulations and thus greatly alleviating overall compu-41 tational cost. There also exist a number of mature software ₄₂ packages for comparative modeling of protein structures, in 43 which a target protein sequence is modeled using one or 44 more structures as templates [CITE Modeller and Rosetta and a recent homology modeling review].

However, it remains difficult for researchers to exploit the full variety of available protein sequence and structural data in simulation studies, largely due to limitations in software architecture. For example, the set up of a biomolecular simulation is typically performed manually, encompassing a series of fairly standard (yet time-consuming) steps such as the choice of protein sequence construct and starting struc-

^{*} Corresponding author; john.chodera@choderalab.org

53 ture, addition of missing residues and atoms, solvation with 107 explicit water and salt buffer, choice of simulation parameters, and system relaxation with energy minimization and one or more short MD simulations. For this reason, simulation studies typically consider only one or a few proteins and starting configurations.

The ability to fully exploit the large base of available protein sequence and structural data in biomolecular simulation studies could open up many interesting avenues for research, enabling the study of entire protein families or superfamilies across multiple organisms. The similarity between members of a given protein family could be exploited to generate arrays of conformational models, which could be used as starting configurations to aid sampling in MD simulations. This approach would be highly beneficial for many MD methods, such as Markov state modeling, which require global coverage of the conformational landscape to realize their full potential, and would also be particularly useful in cases where structural data is present for only a subset of the members of a protein family. It would also aid in studying protein families known to have multiple metastable conformations—such as kinases—, for which the combined body of structural data for the family may cover a large range of these conformations, while the availπ able structures for any individual member might encom-₇₈ pass only one or two distinct conformations.

gap between biomolecular simulation software and omicsscale sequence and structural data: a fully automated open source framework for building simulation-ready protemplate pairs, and several stages of model refinement. 141 identifier for each target protein. As an example application, we have constructed models 142 tices", such as the choice of simulation parameters.

DESIGN AND IMPLEMENTATION

Ensembler is written in Python, and can be used via a command-line tool (ensembler) or via a flexible Python API.

The **Ensembler** modeling pipeline comprises a series of stages which are performed in a defined order. A visual overview of the pipeline is shown in Fig. 1. The various stages of this pipeline are described in detail below.

JDC: We could really help the reader if we preface each 115 section here with a bit of an introduction of what we're trying to accomplish in each stage. Otherwise, I worry that 117 each section is a long list of things we do without refer-118 ence to an overall concept of what the stage is trying to ac-119 complish or why certain decisions were made.] [DLP: Good point. I've added in brief introductions for each section.]

Target selection

The first stage entails the selection of a set of target pro-123 tein sequences.

These targets can be defined manually, simply by providing a FASTA-formatted text file containing the desired target sequences with arbitrary identifiers. The ensembler 127 command-line tool also allows targets to be selected from 128 UniProt—a freely accessible resource for protein sequence 129 and functional data (uniprot.org), using the subcommand gather_targets. The user specifies a query string with 131 the --query flag, which conforms to the same syntax Here, we present the first steps toward bridging the 132 as the search function available on the UniProt website. For example, --query 'mnemonic:SRC_HUMAN' would 134 select the full-length human Src sequence, while --query 'domain: "Protein kinase" AND taxonomy: 9606 AND tein models scalable from single sequences to entire super- 136 reviewed: yes' would select all human protein kinases families. Ensembler provides functions for selecting tar- 137 which have been reviewed by a human curator. In this get sequences and homologous template structures, and 138 way, the user may select a single protein, many proteins, (by interfacing with a number of external packages) per- 139 or an entire superfamily. The program outputs a FASTA forms pairwise alignments, comparative modeling of target- 140 file, setting the UniProt mnemonic (e.g. SRC_HUMAN) as the

In many cases, it will be desirable to build models of for the entire set of human tyrosine kinase catalytic do- 143 an isolated protein domain, rather than the full-length mains, using all available structures of protein kinase do- 144 protein. The gather_targets subcommand allows promains (from any species) as templates. This results in a total 145 tein domains to be selected from UniProt data by passof almost 400,000 models, and we demonstrate that these 146 ing a regular expression string to the --domains flag. provide wide-ranging coverage of known functionally rele- 147 For example, the above --query flag for selecting all vant regions of structure. By using these models as start- 148 human protein kinases returns UniProt entries with doing configurations for highly parallel MD simulations, we 149 main annotations including "Protein kinase", "Protein kiexpect their structural diversity to greatly aid in sampling 150 nase 1", "Protein kinase 2", "Protein kinase; truncated", of conformational space. We anticipate that the tool will 151 "Protein kinase; inactive", "SH2", "SH3", etc. To select prove to be useful in a number of other ways. For example, 152 only domains of the first three types, the following regthe generated models could represent valuable data sets ular expression could be used: 'Protein kinase(?!; even without subsequent production simulation, allowing 154 truncated) (?!; inactive). In this case, target identiexploration of the conformational diversity present within 155 fiers are set with the form [UniProt mnemonic]_D[domain the available structural data for a given protein family. Fur- 156 index], where the latter part represents a 0-based index for thermore, the automation of simulation set up provides an 157 the domain—necessary because a single target protein may excellent opportunity to make concrete certain "best prac- 158 contain multiple domains of interest. Example identifiers: 159 JAK1_HUMAN_DO, JAK1_HUMAN_D1.

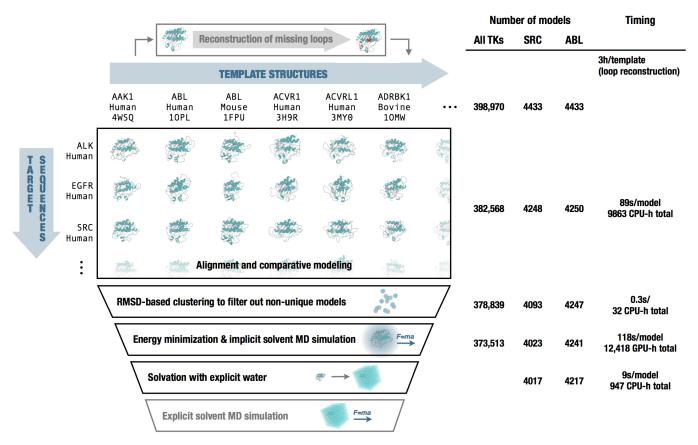

FIG. 1. Diagrammatic representation of the various stages of the Ensembler pipeline. The number of viable models surviving each stage of the pipeline are shown, either for all tyrosine kinases (All TKs) or representative individual kinases (SRC and ABL). In addition, the typical timing on a cluster (containing Intel Xeon E5-2665 2.4GHz hyperthreaded processors and NVIDIA GTX-680 or GTX-Titan GPUs) is reported to exemplify the resources required per model and for modeling the entire set of tyrosine kinases. Note that CPU-h denotes the number of hours consumed by the equivalent of a single hyperthread—parallel execution can reduce wall clock time nearly linearly.

Template selection

160

164

167

175

The second stage entails the selection of templates and 161 storage of associated structures, sequences and identifiers.

This data can be provided manually, by storing the sequences and identifiers in a FASTA file, and the structures as PDB-format coordinate files with filenames matching the identifiers in the sequence file. The structure residues must also match those in the sequence file.

The ensembler gather_templates subcommand also provides methods for selecting template structures from either UniProt or the Protein Data Bank (PDB;), specified by the --gather_from flag. Both methods select templates at the level of PDB chains—a PDB structure containing multiple chains with identical sequence spans (e.g. for crystal unit cells with multiple asymmetric units) would thus give rise to multiple template structures.

--query 2H8H,1Y57. 181 server, as well as associated data from the SIFTS service 204 selection from the PDB. If the --domains flag is used, then

182 (www.ebi.ac.uk/pdbe/docs/sifts) (CITE: Velankar Nucleic Acids Res 2013), which provides residue-level mappings between PDB and UniProt entries. The SIFTS data is used to extract template sequences, retaining only residues which are resolved and match the equivalent residue in the UniProt 187 sequence—non-wildtype residues are thus removed from the template structures. Furthermore, PDB chains with less than a given percentage of resolved residues (default: 70%) are filtered out. Sequences are stored in a FASTA file, with identifiers of the form [UniProt mnemonic]_D[UniProt domain index]_[PDB ID]_[PDB chain ID], 193 SRC_HUMAN_DO_2H8H_A. Matching residues then extracted from the original coordinate files and stored as 195 PDB-format coordinate files.

Selection of templates from UniProt proceeds in a similar fashion as for target selection; the --query flag is used to 198 select full-length proteins from UniProt, while the optional Selection of templates from the PDB simply requires 199 --domains flag allows selection of individual domains with passing a list of PDB IDs as a comma-separated string, 200 a regular expression string. The returned UniProt data for Specific PDB chain IDs 201 each protein includes a list of associated PDB chains and can optionally also be selected via the --chainids 202 their residue spans, and this information is used to select The program retrieves structures from the PDB 203 template structures, using the same method as for template

It's a good idea to suggest that this is an impor315 tant first step toward enabling superfamily- and genomicsscale modeling, but there's a lot of work yet to be done.]

Packaging

Ensembler provides a packaging module which can be used to compress models in preparation for data transfer, or to prepare models with the appropriate directory and file structure for subsequent production simulations on the distributed computing platform Folding@home (CITE: F@H).

Provenance

323

To aid the user in tracking the provenance of each model, each pipeline function also outputs a metadata file, which elps to link data to the software version used to generate it (both **Ensembler** and its dependencies), and also provides timing and performance information, and other data such as hostname.

Rapidly modeling a single template

For users interested in simply using **Ensembler** to rapidly generate a set of models for a single template sequence, Ensembler provides a command-line tool quickmodel, which performs the entire pipeline for a single target with a small number of templates. For larger numbers of models (such as entire protein families), modeling time is greatly reduced by using the main modeling pipeline, which is parallelized via MPI, distributing computation across each model (or across each template, in the case of the loop reconstruction code), and scaling (in a "pleasantly parallel" manner) up to the number of models generated.

III. RESULTS

As a first application of **Ensembler**, we have built models for all 90 human tyrosine kinase (TKs) domains listed in UniProt. TKs (and protein kinases in general) play important roles in many cellular processes and are involved in a number of types of cancer. For example, mutations of Src are associated with colon, breast and prostate cancer [CITE: Src cancer involvement], while a translocation between the TK Abl and the pseudokinase Bcr is closely associated with 383 ploit the full body of available genomic and structural data 393 55-100% range.

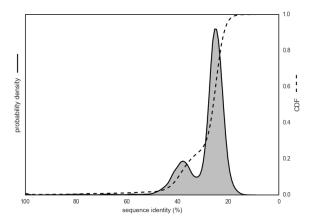

FIG. 2. Sequence identity distribution for human TK models. Distribution of sequence identities for all 373,513 models generated for the human tyrosine kinases. [DLP: should I mention the use of KDE smoothing?] Sequence identities are calculated from pairwise target-template alignments. The cumulative distribution function is shown by the dashed line.

within the kinase family, e.g. by generating large numbers of 362 starting configurations to be used in highly parallel MD simulation.

We selected all available structures of protein kinase do-365 mains (of any species) as templates, for a total of 4433 366 (398,970 target-template pairs). The templates were de-367 rived from 3028 individual PDB entries and encompassed 23 different species, with 3634 template structures from human kinase constructs.

The templates were first subjected to loop remodeling, using the loopmodel subcommand. Out of 3666 templates with one or more missing residues, 3134 were successfully 373 remodeled.

Following loop remodeling, the **Ensembler** pipeline was performed up to and including the implicit solvent MD refinement stage, which completed with 373,513 surviving models. In addition, the solvation stage was performed for two representative individual kinases (Src and Abl). The number of models which survived each stage are shown in Fig. 1, indicating that the greatest attrition occurred during the modeling stage. Fig. 1 also indicates the typical timing 382 achieved on a cluster for each stage.

The distribution of RMSDs of the final models (relative to chronic myelogenous leukemia [CITE: Abl cancer involve- 384 the highest sequence identity model for a given target) is ment]. Protein kinase domains are thought to have multi- 385 shown in Fig. 3. The distributions are stratified based on ple accessible metastable conformation states, with a sin- 386 the sequence identity between target and template, indicatgle active conformation, and much effort is directed at de- 387 ing that higher sequence identity templates result in lower veloping kinase inhibitor drugs which bind to and stabilize 388 RMSD models. The sequence identity stratifications were inactive conformations [CITE: Lee and Craik Science 2009]. selected based on the sequence identity distribution (Fig. Kinases are thus a particularly interesting subject for study 390 2), which suggests an intuitive division into three categories, with MSM methods [CITE: recent kinase MSM papers], and with 307,753 models in the 0-35% sequence identity range, this approach could benefit greatly from the ability to ex- 392 69.922 models in the 35-55% range, and 4893 models in the

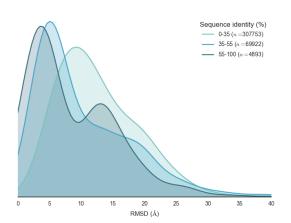

FIG. 3. RMSD distribution by sequence identity. RMSD distributions for all 373,513 human TK models, divided into three sequence identity ranges. For a given target, model RMSDs are calculated relative to the highest sequence identity model for that target.

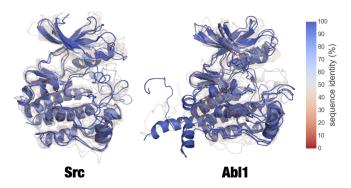

FIG. 4. Superposition of clustered models of Src and Abl. Superposed renderings of nine models each for Src and Abl, giving some indication the diversity of conformations generated by Ensembler. The models for each target were divided into three sequence identity ranges (as in Fig. 3), and RMSD-based k-medoids clustering was performed to select three clusters from each. The models shown are the centroids of each cluster. Models are colored and given transparency based on their sequence identity, so that high sequence identity models are blue and opaque, while lower sequence identity models are transparent and red.

IV. AVAILABILITY AND FUTURE DIRECTIONS

The latest release of **Ensembler** can be installed via the conda package manager for Python [?].

7 # conda install -c https://conda.binstar.org/omnia ensembler
8 Up to date instructions can be found at https://github.
9 com/choderalab/ensembler. This will install all dependencies except for Modeller and (optionally) Rosetta, which are not available through the conda package manager, and thus must be installed separately by the user. The latest source can be downloaded from the above GitHub repostitory, which also contains instructions for building and installing the code.

V. ACKNOWLEDGMENTS

The authors are grateful to Kyle A. Beauchamp (MSKCC), Robert McGibbon (Stanford), Arien S. Rustenburg (MSKCC) for many excellent software engineering suggestions. The authors thank Sonya M. Hanson (MSKCC), Nicholas M. Levinson (?), Markus A. Seeliger (Stony Brook), Diwakar Shukla (Stanford), and Avner Schlessinger (Mount Sinai) for help-ful scientific feedback on modeling kinases. The authors are grateful to Benjamin Webb and Andrej Sali (UCSF) for help with the MODELLER package, Peter Eastman and Vijay Pande (Stanford) for assistance with OpenMM, and Marilyn Gunner (CCNY) for assistance with MCCE2. DLP and this work was supported in part by the generous support of a Louis V. Gerstner Young Investigator Award.

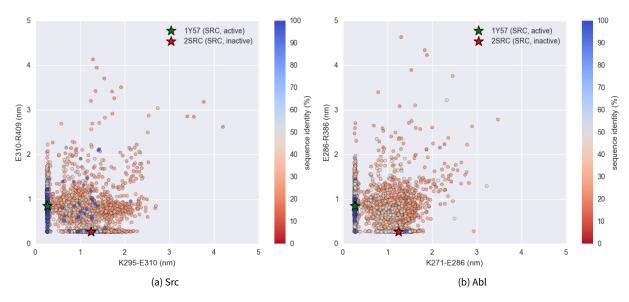

FIG. 5. E310-R409 and K295-E310 distances for models of Src and Abl, colored by sequence identity.

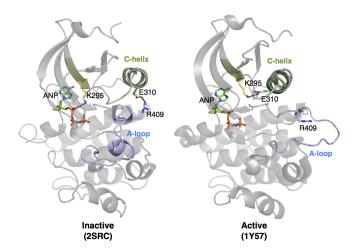

FIG. 6. Two structures of Src, indicating certain residues involved in activation. In the inactive state, E310 forms a salt bridge with R409. During activation, the C-helix (green) moves and rotates, orienting E310 towards the ATP-binding site and allowing it to instead form a salt bridge with K295. This positions K295 in the appropriate position for catalysis.
