The rapidly expanding body of available genomic and protein structural data provides a rich resource for understanding protein dynamics with biomolecular simulation. While computational infrastructure has grown rapidly, simulations on an omics scale are not yet widespread, primarily because software infrastructure to enable simulations at this scale has not kept pace. It should now be possible to study protein dynamics across entire (super)families, exploiting both available structural biology data and conformational similarities across homologous proteins. Here, we present a new tool for enabling high-throughput simulation in the genomics era. Ensembler takes any set of sequences—from a single sequence to an entire superfamily and shepherds them through various stages of modeling and refinement to produce simulation-ready structures. This includes comparative modeling to all relevant PDB structures (which may span multiple conformational states of interest), reconstruction of missing loops, addition of missing atoms, culling of nearly identical structures, assignment of appropriate protonation states, solvation in explicit solvent, and refinement and filtering with molecular simulation to ensure stable simulation. The output of this pipeline is an ensemble of structures ready for subsequent molecular simulations using computer clusters, supercomputers, or distributed computing projects like Folding@home. Ensembler thus automates much of the timeconsuming process of preparing protein models suitable for simulation, while allowing scalability up to entire superfamilies. A particular advantage of this approach can be found in the construction of kinetic models of conformational dynamics—such as Markov state models (MSMs)—which benefit from a diverse array of initial configurations that span the accessible conformational states to aid sampling. We demonstrate the power of this approach by constructing models for all catalytic domains in the human tyrosine kinase family, using all available kinase catalytic domain structures from any organism as structural templates.

Ensembler is free and open source software licensed under the GNU General Public License (GPL) v2. It should run on all major operating systems, and has been tested on Linux and OS X. The latest release can be installed via the conda package manager, and the latest source can be downloaded from https://github.com/choderalab/ensembler.

Keywords: molecular dynamics simulation; comparative modeling; distributed simulation

I. INTRODUCTION

Recent advances in genomics and structural biology have helped generate an enormous wealth of protein data at the level of amino-acid sequence and three-dimensional structure. However, proteins typically exist as an ensemble of thermally accessible conformational states, and static structures provide only a snapshot of their rich dynamical behavior. Many functional properties—such as the ability to bind small molecules or interact with signaling partners—require transitions between states, encompassing anything from reorganization of sidechains at binding interfaces to domain motions to large scale folding-unfolding events. Drug discovery could also benefit from a more extensive consideration of protein dynamics, whereby small molecules might be selected based on their predicted ability to bind and trap a protein target in an inactive state [1].

Molecular dynamics (MD) simulations have the capabilMolecular dynamics (MD) simulations have the capabilJity, in principle, to describe the time evolution of a protein in atomistic detail, and have proven themselves to be a useful tool in the study of protein dynamics. A number of mature software packages and forcefields are now available, and much recent progress has been driven by advances in computing architecture. For example, many MD

29 packages are now able to exploit GPUs [2, 3], which pro-30 vide greatly improved simulation efficiency per unit cost rel-31 ative to CPUs, while distributed computing platforms such 32 as Folding@home [4], Copernicus [5], and GPUGrid [6], al-33 low scalability on an unprecedented level. In parallel, meth-34 ods for building human-understandable models of protein 35 dynamics from noisy simulation data, such as Markov state modeling (MSM) approaches, are now reaching maturity [7– ³⁷ 9]. MSM methods in particular have the advantage of be-38 ing able to aggregate data from multiple independent MD 39 trajectories, facilitating parallelization of production simu-40 lations and thus greatly alleviating overall computational 41 cost. There also exist a number of mature software packages 42 for comparative modeling of protein structures, in which a 43 target protein sequence is modeled using one or more struc-44 tures as templates [10, 11].

However, it remains difficult for researchers to exploit the full variety of available protein sequence and structural data in simulation studies, largely due to limitations in software architecture. For example, the set up of a biomolecular simulation is typically performed manually, encompassing a series of fairly standard (yet time-consuming) steps such as the choice of protein sequence construct and starting structure(s), addition of missing residues and atoms, solvation with explicit water and counterions (and potentially buffer components and cosolvents), choice of simulation parameters (or parameterization schemes for components where

^{*} Corresponding author; john.chodera@choderalab.org

minimization, and one or more short preparatory MD sim- 115 URL of where to get the code and TK models here?] ulations to equilibrate the system and relax the simulation cell. Due to the laborious and manual nature of this process, simulation studies typically consider only one or a few proteins and starting configurations. Worse still, studies (or collections of studies) that do consider multiple proteins often suffer from the lack of consistent best practices in this preparation process, making comparisons between related proteins unnecessarily difficult.

The ability to fully exploit the large quantity of available protein sequence and structural data in biomolecular simulation studies could open up many interesting avenues for research, enabling the study of entire protein families or superfamilies within a single organism or across multiple organisms. The similarity between members of a given protein family could be exploited to generate arrays of conformational models, which could be used as starting configurations to aid sampling in MD simulations. This approach would be highly beneficial for many MD methods, such as MSM construction, which require global coverage of the conformational landscape to realize their full potential, and would also be particularly useful in cases where structural data is present for only a subset of the members of a protein family. It would also aid in studying protein families known to have multiple metastable conformations—such as kinases—for which the combined body of structural data for the family may cover a large range of these conformations, while the available structures for any individual member might encompass only one or two distinct conformations.

Here, we present the first steps toward bridging the gap between biomolecular simulation software and omicsscale sequence and structural data: a fully automated open source framework for building simulation-ready protein models in multiple conformational substates scalable from single sequences to entire superfamilies. **Ensembler** provides functions for selecting target sequences and homologous template structures, and (by interfacing with a number of external packages) performs pairwise alignments, comparative modeling of target-template pairs, and several stages of model refinement. As an example application, we have constructed models for the entire set of human tyrosine kinase catalytic domains, using all available structures of protein kinase domains (from any species) as templates. This results in a total of almost 400,000 models, and we demonstrate that these provide wide-ranging coverage of known functionally relevant conformations. By using these models as starting configurations for highly parallel MD simulations, we expect their structural diversity to greatly aid in sampling of conformational space.

We anticipate that the tool will prove to be useful in a 158 number of other ways. For example, the generated models could represent valuable data sets even without subtural data for a given protein family. Furthermore, the au- 163 of the first three types, the following regular expression tomation of simulation set up provides an excellent oppor- 164 could be used: 'Protein kinase(?!; truncated)(?!;

DESIGN AND IMPLEMENTATION

Ensembler is written in Python, and can be used via a command-line tool (ensembler) or via a flexible Python API 119 to allow integration of its components into other applica-

The **Ensembler** modeling pipeline comprises a series of 122 stages which are performed in a defined order. A visual overview of the pipeline is shown in Fig. 1. The various stages of this pipeline are described in detail below.

Target selection and retrieval

The first stage entails the selection of a set of target protein sequences—the sequences the user is interested in generating simulation-ready structural models for. This may be 129 a single sequence—such as a full-length protein or a con-130 struct representing a single domain—or a collection of sequences, such as a particular domain from an entire family of proteins. The output of this stage is a FASTA-formatted text file containing the desired target sequences with corresponding arbitrary identifiers.

The ensembler command-line tool allows targets to be selected from UniProt—a freely accessible resource for protein sequence and functional data (uniprot.org) [12]— 138 via a UniProt search guery. To retrieve target sequences 139 from UniProt, the subcommand gather_targets us used with the --query flag followed by a UniProt query 141 string conforming to the same syntax as the search 142 function available on the UniProt website. For exam---query 'mnemonic:SRC_HUMAN' would select 143 ple, the full-length human Src sequence, while --query 'domain: "Protein kinase" AND organism: "homo $_{\mbox{\scriptsize 146}}$ sapiens" AND reviewed:yes' would select all human protein kinases which have been reviewed by a human 148 curator. In this way, the user may select a single protein, many proteins, or an entire superfamily from UniProt. 150 The program outputs a FASTA file, setting the UniProt mnemonic (e.g. SRC_HUMAN) as the identifier for each target 152 protein.

In many cases, it will be desirable to build models of an isolated protein domain, rather than the full-length pro-155 tein. The gather_targets subcommand allows protein domains to be selected from UniProt data by passing a regular expression string to the --uniprot_domain_regex flag. For example, the above --query flag for selecting all human protein kinases returns UniProt entries with domain annotations including "Protein kinase", "Protein kinase 1", sequent production simulation, allowing exploration of the 🔐 "Protein kinase 2", "Protein kinase; truncated", "Protein kiconformational diversity present within the available struc- 162 nase; inactive", "SH2", "SH3", etc. To select only domains 113 tunity to make concrete certain "best practices", such as the 165 inactive)'. If the --uniprot_domain_regex flag is

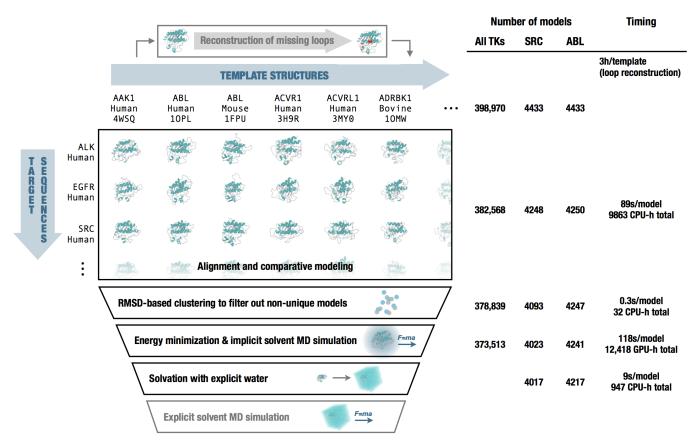

FIG. 1. Diagrammatic representation of the various stages of the Ensembler pipeline and illustrative statistics for modeling all human tyrosine kinase catalytic domains. On the left, the various stages of the Ensembler pipeline are shown. On the right, the number of viable models surviving each stage of the pipeline is shown for modeling all 90 tyrosine kinases (All TKs) and representative individual tyrosine kinases (SRC and ABL). Typical timings on a computer cluster (containing Intel Xeon E5-2665 2.4GHz hyperthreaded processors and NVIDIA GTX-680 or GTX-Titan GPUs) is reported to illustrate resource requirements per model for modeling the entire set of tyrosine kinases. Note that CPU-h denotes the number of hours consumed by the equivalent of a single CPU hyperthread and GPU-h on a single GPU—parallel execution via MPI reduces wall clock time nearly linearly.

166 used, target identifiers are set with the form [UniProt 185 the same protein family as the targets, guaranteeing some mnemonic]_D[domain index], where the latter part repre- 186 degree of homology between targets and templates. sents a 0-based index for the domain—necessary because a 187 est (e.g. JAK1_HUMAN_DO, JAK1_HUMAN_D1).

Target sequences can also be defined manually (or from another program) by providing a FASTA-formatted text file containing the desired target sequences with corresponding arbitrary identifiers.

Template selection and retrieval

175

The ensembler gather_templates subcommand prosingle target protein may contain multiple domains of inter- 188 vides methods for selecting template structures from either UniProt or the PDB (http://www.rcsb.org/pdb), speci-190 fied by the --gather_from flag. Both methods select templates at the level of PDB chains—a PDB structure containing multiple chains with identical sequence spans (e.g. for 193 crystal unit cells with multiple asymmetric units) would thus 194 give rise to multiple template structures.

Selection of templates from the PDB simply requires 196 passing a list of PDB IDs as a comma-separated string, e.g. --query 2H8H, 1Y57. Specific PDB chain IDs can Ensembler uses comparative modeling to build models, 198 optionally also be selected via the --chainids flag. and as such requires a set of structures to be used as tem- 199 The program retrieves structures from the PDB server, plates. The second stage thus entails the selection of tem- 200 as well as associated data from the SIFTS service plates and storage of associated sequences, structures, and 201 (www.ebi.ac.uk/pdbe/docs/sifts) [13], which provides identifiers. These templates can be specified manually, or 202 residue-level mappings between PDB and UniProt entries. using the ensembler gather_templates subcommand to 203 The SIFTS data is used to extract template sequences, automatically select templates based on a search of the 204 retaining only residues which are resolved and match Protein Data Bank (PDB) or UniProt. A recommended ap- 205 the equivalent residue in the UniProt sequence—non-184 proach is to select templates from UniProt which belong to 206 wildtype residues are thus removed from the template

structures. Furthermore, PDB chains with less than a 262 sion. Furthermore, the Rosetta loopmodel program will not filtered out. Sequences are stored in a FASTA file, with iden- 264 residues spans are modeled in the subsequent stage. tifiers of the form [UniProt mnemonic]_D[UniProt domain index]_[PDB ID]_[PDB chain ID], SRC_HUMAN_DO_2H8H_A. Matching residues tracted from the original coordinate files and stored as PDB-format coordinate files.

Selection of templates from UniProt proceeds in a similar fashion as for target selection; the --query flag is used select full-length proteins from UniProt, while the optional --uniprot_domain_regex flag allows selection of ndividual domains with a regular expression string. The returned UniProt data for each protein includes a list of associated PDB chains and their residue spans, and this information is used to select template structures, using the same method as for template selection from the PDB. Only structures solved by X-ray crystallography or NMR are selected, thus excluding computer-generated models available from the PDB. If the --uniprot_domain_regex flag is used, then templates are truncated at the start and end of the domain sequence.

Templates can also be defined manually. Manual specification of templates simply requires storing the sequences and arbitrary identifiers in a FASTA file, and the structures as PDB-format coordinate files with filenames matching the identifiers in the sequence file. The structure residues must also match those in the sequence file.

220

235

Template refinement

Unresolved template residues can optionally be modeled into template structures with the loopmodel subcommand, which employs a kinematic closure algorithm provided via the loopmodel tool of the Rosetta software suite [14, 15]. Because fewer loops need to be built during the subsequent target model-building stage, we find that prebuilding template loops tends to provide higher-quality models after completion of the **Ensembler** pipeline. [JDC: Should we cite ur evidence for this with the TKs, or maybe tone back the claim a bit to say that it is possible this could make things asier?] [DLP: Sikander mentioned to me that someone has developed an algorithm called pokefind (or knotfind, which I think is an earlier version) which aims to find knots in proteins, of the type which encouraged us to use Rosetta to reconstruct template loops. DOI: 10.1093/bioinformatics/btp198 It sounds like these algorithms have actually been implemented in Rosetta, so this could explain why Rosetta seems to do better at avoiding making these knotted strucures. Would be useful to check this out further first, and then decide whether or not to discuss the knotted structures in the manuscript.]

Loop remodeling may fail for a small proportion of templates due to spatial constraints imposed by the original 310 structure; the subsequent modeling step thus automati- 311 PDB structures as individual templates, a number of modcally uses the remodeled version of a template if available, 312 els may be generated with very similar structures if these but otherwise falls back to using the non-remodeled ver- 313 individual chains are nearly identical in conformation. For

given percentage of resolved residues (default: 70%) are 263 model missing residues at the termini of a structure—such

Modeling

In the modeling stage, structural models of the target se-267 quence are generated from the template structures, with 268 the goal of modeling the target in a variety of conforma-269 tions that could be significantly populated under equilibrium conditions.

Modeling is performed using the automodel function of 272 the Modeller software package [16, 17] to rapidly generate 273 a single model of the target sequence from each template 274 structure. Modeller uses simulated annealing cycles along 275 with a minimal forcefield and spatial restraints—generally Gaussian interatomic probability densities extracted from 277 the template structure with database-derived statistics de-278 termining the distribution width—to rapidly generate can-279 didate structures of the target sequence from the provided template sequence [16, 17].

While Modeller's automodel function can generate its own alignments automatically, a standalone function was preferable for reasons of programming convenience. As such, we implemented pairwise alignment functionality us-285 ing the the BioPython pairwise2 module [18]—which uses 286 a dynamic programming algorithm—with the PAM 250 scor-287 ing matrix of Gonnet et al. [19]. The alignments are car-288 ried out with the align subcommand, prior to the modeling step which is carried out with the build_models subcommand. The align subcommand also writes a list of the sequence identities for each template to a text file, and this can be used to select models from a desired 293 range of sequence identities. The build_models sub-294 command and all subsequent pipeline functions have a --template_segid_cutoff flag which can be used to se-296 lect only models with sequence identities greater than the 297 given value.

Models are output as PDB-format coordinate files. To 299 minimize file storage requirements, Ensembler uses the Python gzip library to apply compression to all sizeable text files from the modeling stage onwards. The restraints used 302 by Modeller could potentially be used in alternative addi-303 tional refinement schemes, and **Ensembler** thus provides 304 a flag (--write_modeller_restraints_file) for option-305 ally saving these restraints to file. This option is turned off by default, as the restraint files are relatively large (e.g. \sim 400 307 KB per model for protein kinase domain targets), and are 308 not expected to be used by the majority of users.

Filtering of nearly identical models

Because **Ensembler** treats individual chains from source

314 this reason, and also to allow users to select for high di- 369 along with a modified generalized Born solvent model [30] versity if they so choose, **Ensembler** provides a way to fil- 370 as implemented in the OpenMM package [2]. tain only a single model per cluster.

Refinement of models

326

While the utility of comparative modeling methods has 328 been greatly enhanced by the recent explosion in the availability of protein structural data, the structures generated are generally considered "low-resolution" in comparison to those derived using experimental techniques such as X-ray crystallography. RMS errors of \sim 3 Åfor C_{α} atoms relative to a native crystal structure are typical [25-27]. A number of refinement methods have been developed to help steer homology models toward more "native-like" conformations [26, 27], of which MD simulations are an important example. While long-timescale unrestrained MD simulations (on the order of 100 μ s) have been found to be ineffective for recapitulating native-like conformations, possibly due to forcefield issues [25], even relatively short simas sidechain orientation [27].

quality, this also prepares models for subsequent produc- 396 68th percentile). This helps to prevent models with parmolecules, if desired.

We also 380 draw attention to a recent paper which indicates that lower 381 Langevin collision rates may result in faster phase space ex-382 ploration [31].

Solvation and NPT equilibration

While protein-only models may be sufficient for struc-385 tural analysis or implicit solvent simulations, **Ensembler** 386 also provides a stage for solvating models with explicit wa-387 ter and performing a round of explicit-solvent MD refinement/equilibration under isothermal-isobaric (NPT) conditions. The solvation step solvates each model for a given target with the same number of waters to facilitate the inulations can be useful for relaxing structural elements such 391 tegration of data from multiple simulations, which is impor-392 tant for methods such as the construction of MSMs. The Ensembler thus includes a refinement module, which 393 target number of waters is selected by first solvating each uses short molecular dynamics simulations to refine the 394 model with a specified padding distance (default: 10 Å), models built in the previous step. Packaging

420 421 can be used to prepare models for other uses. The 422 package_models subcommand currently provides functions (specified via the --package_for flag) for compressing models in preparation for data transfer, or for organizing them with the appropriate directory and file structure for production simulation on the distributed computing platform Folding@home [4]. The module could easily be extended to add methods for preparing models for other purposes. For example, production simulations could alternatively be run using Copernicus [5]—a framework for performing parallel adaptive MD simulations— 432 or GPUGrid [6]—a distributing computing platform which ₄₃₃ relies on computational power voluntarily donated by the ⁴⁷⁹ owners of nondedicated GPU-equipped computers.

Other features

Tracking provenance information

To aid the user in tracking the provenance of each model, 438 each pipeline function also outputs a metadata file, which helps to link data to the software version used to generate it (both **Ensembler** and its dependencies), and also provides timing and performance information, and other data such as hostname.

Rapidly modeling a single template

sembler provides a command-line tool quickmodel, which performs the entire pipeline for a single target with a small number of templates. For larger numbers of models (such as entire protein families), modeling time is greatly reduced by using the main modeling pipeline, which is parallelized via MPI, distributing computation across each model (or across each template, in the case of the loop reconstruction code), and scaling (in a "pleasantly parallel" manner) up to the number of models generated.

III. RESULTS

Modeling of all human tyrosine kinase catalytic domains

As a first application of **Ensembler**, we have built mod-457 els for the human tyrosine kinase (TK) family. [JDC: Is there a complete list of these somewhere? Maybe reference supplementary data?] TKs (and protein kinases in general) play 462 in a number of types of cancer [34]. For example, muta- 517 correlation between remodeling failures and the number of 463 tions of Src are associated with colon, breast, prostate, lung, 518 missing residues (Fig. 2, top); templates for which remodel-

and pancreatic cancers [35], while a translocation between the TK Abl1 and the pseudokinase Bcr is closely associated **Ensembler** provides a packaging module which 466 with chronic myelogenous leukemia [36]. Protein kinase do-467 mains are thought to have multiple accessible metastable 468 conformation states, and much effort is directed at developing kinase inhibitor drugs which bind to and stabilize inactive conformations [37]. Kinases are thus a particularly interesting subject for study with MSM methods [38], and this approach stands to benefit greatly from the ability to exploit the full body of available genomic and structural data within the kinase family, e.g. by generating large numbers of starting configurations to be used in highly parallel MD simula-

> We selected all 90 TK domains annotated in UniProt as targets, using the following command:

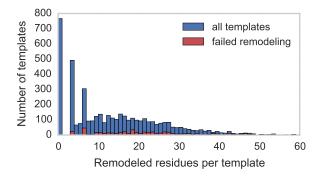

gather_targets --query 'family:"tyr protein kinase family" AND 480 organism: "homo sapiens" AND reviewed: yes' --uniprot_domain_regex 481 '^Protein kinase(?!; truncated)(?!; inactive)' 482 The 'reviewed:yes' expression in the UniProt query 483 ensured that only UniProt entries which have been re-484 viewed by a human expert were included in the results. The --uniprot_domain_regex regular expression resulted 486 in the selection of domains annotated "Protein kinase", "Protein kinase 1", and "Protein kinase 2", while excluding domains "Protein kinase; truncated", "Protein kinase; inactive", "Alpha-type protein kinase", and many types of non-kinase domain. We selected all available structures of protein kinase domains (of any species) as templates, using 492 the following command: 493 gather_templates --gather_from uniprot --query 'domain: "Protein

494 kinase" AND reviewed:yes' --uniprot_domain_regex '^Protein 495 kinase(?!; truncated)(?!; inactive),

496 This returned 4433 templates, giving a total of 398,970 497 target-template pairs. The templates were derived from For users interested in simply using **Ensembler** to rapidly 498 3028 individual PDB entries and encompassed 23 different generate a set of models for a single template sequence, En- 499 species, with 3634 template structures from human kinase 500 constructs.

Ensembler modeling statistics

Crystallographic structures of kinase catalytic domains 503 generally contain a significant number of missing residues (median 11, standard deviation 13, max 102) due to the high mobility of several loops (Fig. 2, top), with a number of these missing spans being significant in length (median 5, standard deviation 6, max 82; Fig. 2, bottom). To reduce the reliance on the Modeller rapid model construction stage to reconstruct very long unresolved loops, unresolved template residues were first remodeled using the loopmodel subcommand. Out of 3666 templates with one or more missing residues, 3134 were successfully remodeled by the 513 Rosetta loop modeling stage (with success defined simply as ₅₁₄ program termination with out error); most remodeling failures were attributable to unsatisfiable spatial constraints important roles in many cellular processes and are involved 516 imposed by the original template structure. There was some

FIG. 2. FIG. 3. Template-target sequence identity distribution for human tyrosine kinase catalytic domains. Sequence identities are calculated from all pairwise target-template alignments, where targets are human kinase catalytic domain sequences and templates are all kinase catalytic domains from any organism with structures in the PDB, as described in the text. A kernel density estimate of the target-template sequence identity probability density function is shown as a solid line with shaded region, while the corresponding cumulative distribution function is shown as a dashed line.

Evaluation of model quality and utility

All tyrosine kinases

To evaluate the variety of template sequence similarities finement stage, which completed with 373.513 (94%) sur- 550 relative to each target sequence, we calculated sequence viving models across all TKs. To obtain statistics for the sol- ssi identity distributions, as shown in Fig. 3. This suggests an intuitive division into three categories, with 307,753 moddinate data (with solvated PDB coordinate files taking up 553 els in the 0-35% sequence identity range, 69,922 models in about 0.9 MB each), the solvate subcommand was per- 554 the 35-55% range, and 4893 models in the 55-100% range. formed for two representative individual kinases (Src and 555 We then computed the RMSD distributions for the models 556 created for each target (relative to the model derived from The number of models which survived each stage are 557 the template with highest sequence identity) Fig. 4, to asshown in Fig. 1, indicating that the greatest attrition oc- 558 sess the diversity of conformations captured by the modcurred during the modeling stage. The number of re- 559 eling pipeline. Furthermore, to understand the influence fined models for each target ranged from 4005 to 4248, 560 of sequence identity on the conformational similarities of with a median of 4160 and standard deviation of 60. 561 the resulting models, the RMSD distributions were strati-Fig. 1 also indicates the typical timing achieved on a clus- 562 fied based on the three sequence identity categories deter for each stage, showing that the build_models and 563 scribed above. This analysis indicates that higher sequence refine_implicit_md stages are by far the most compute- 564 identity templates result in models with lower RMSDs, while 565 templates with remote sequence identities result in larger

We also analyzed the potential energies of the models generated per model breaks down as 39 kB for the output 559 These ranged from -14180 kT to -3590 kT, with a median

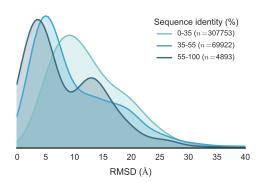

FIG. 4. Distribution of RMSDs to all TK catalytic domain models relative to the model derived from the highest sequence identity template. Distributions are built from data from all 90 TK targets. To better illustrate how conformational similarity depends on sequence identity, the lower plot illustrates the distributions as stratified into three sequence identity classes: high identity (55-100%), moderate identity (35–55%), and remote identity (0–35%). The plotted distributions have been smoothed using kernel density estimation.

571 distributions—stratified using the same sequence identity ranges as above—are plotted in Fig. 5, indicating that higher sequence identity templates tend to result in slightly lower energy models. Of the 25,457 models which failed to complete the implicit refinement MD stage, all except 9 failed within the first 1 ps of simulation.

[JDC: This section looks pretty anemic. What other kinds of analyses can we do for all the TKs? There is so much data here! There must be something neat we can do to examine it, right?]

[DLP: for further analysis, a good option might be to try to make a more rigorous assessment of model quality via comparison to reference crystal structures, based on features such as RMSD, phi/psi angles, H-bonds etc. We could also 585 try using the Rosetta heuristic scoring function for this pur-586 pose.]

Src and Abl1

587

generated, we have analyzed two example TKs (Src and Abl1) 602 ranges, based on the structure of the sequence identity dis-

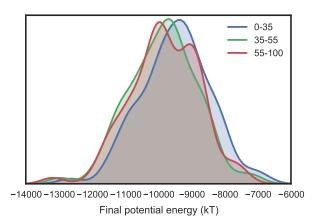

FIG. 5. Distribution of final energies from implicit solvent MD refinement of TK catalytic domain models. To illustrate how the energies are affected by sequence identity, the models are separated into three sequence identity classes: high identity (55–100%), moderate identity (35-55%), and remote identity (0-35%). The plotted distributions have been smoothed using kernel density estimation.

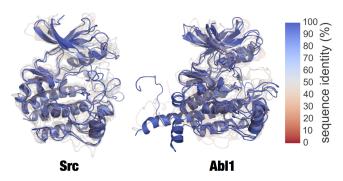

FIG. 6. Superposition of clustered models of Src and Abl1. Superposed renderings of nine models each for Src and Abl1, giving some indication the diversity of conformations generated by Ensembler. The models for each target were divided into three sequence identity ranges (as in Fig. 4), and RMSD-based k-medoids clustering was performed to select three clusters from each. The models shown are the centroids of each cluster. Models are colored and given transparency based on their sequence identity, so that high sequence identity models are blue and opaque, while lower sequence identity models are transparent and red.

590 in detail. Due to their importance in cancer, these kinases have been the subject of numerous studies, encompassing many different methodologies. In terms of structural data, ₅₉₃ a large number of crystal structures have been solved (with or without ligands such as nucleotide substrate or inhibitor drugs), showing the kinases in a number of different conformations. These two kinases are thus also interesting targets 597 for MSM studies, with one recent study focusing on modeling the states which constitute the activation pathway of Src [38].

Fig. 6 shows a superposition of a set of representative To provide a more complete evaluation of the models of Src and Abl1. Models were first stratified into three $_{603}$ tribution (Fig. 3), then subjected to k-medoids clustering to pick three representative models from each sequence identity range. [JDC: Explain how k-medoids clustering was done either here or in figure caption.] Each model is colored and given a transparency based on the sequence identity between the target and template sequence. The figure gives an idea of the variance present in the generated models. High sequence identity models (in opaque blue) tend to be guite structurally similar, with some variation in loops or changes in domain orientation.

613

The Abl1 renderings in Fig. 6 indicate one high sequence identity model with a long unstructured region at one of the termini, which was unresolved in the original template structure. While such models are not necessarily incorrect or undesirable, it is important to be aware of the effects they may have on production simulations performed under periodic boundary conditions, as long unstructured termini can be prone to interact with a protein's periodic image. Lower sequence identity models (in transparent white or red) indicate much greater variation in all parts of the structure. We believe the mix of high and low sequence identity models to be particularly useful for methods such as MSM building, which require thorough sampling of the conformational landscape. The high sequence identity models could be 660 considered to be the most likely to accurately represent true metastable states. Conversely, the lower sequence identity models could be expected to help push a simulation into regions of conformation space which might take intractably long to reach if starting a single metastable conformation.

To evaluate the models of Src and Abl1 in the context of the 664 http://github.com/choderalab/ensembler 683 published structural biology literature on functionally rele- 665 The latest release of **Ensembler** can be installed via vant conformations, we have focused on two residue pair 666 the conda package manager for Python [http://conda. distances thought to be important for the regulation of pro- 667 pydata.org]: tein kinase domain activity. We use the residue numbering schemes for chicken Src (which is commonly used in the 669 conda ensembler man Abl1 isoform A [41–43] respectively; the exact numbering schemes are provided in Supporting Information S1.

Fig. 7 shows two structures of Src believed to represent inactive (PDB code: 2SRC) [39] and active (PDB code: 1Y57) [40] states. One notable feature which distinguishes the two structures is the transfer of an electrostatic interaction of E310 from R409 (in the inactive state) to K295 (in the active state), brought about by a rotation of the α C-helix. These three residues are also well conserved [44], and a number of experimental and simulation studies have suggested that this electrostatic switching process plays a role in a regulatory mechanism shared across the protein kinase 679 simulation, could greatly aid in sampling of functionally rel- ssr scale modeling, but there's a lot of work yet to be done.] 659 evant conformational states.

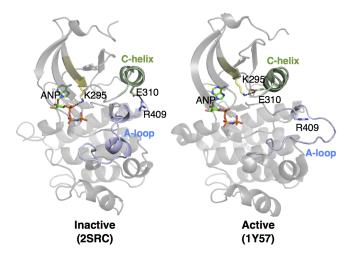

FIG. 7. Two structures of Src, indicating certain residues involved in activation. In the inactive state, E310 forms a salt bridge with R409. During activation, the α C-helix (green) moves and rotates, orienting E310 towards the ATP-binding site and allowing it to instead form a salt bridge with K295. This positions K295 in the appropriate position for catalysis.

AVAILABILITY AND FUTURE DIRECTIONS

Availability

The code for **Ensembler** is hosted on the collaborative open source software development platform GitHub,

668 conda config -add channels https://conda.binstar.org/omnia

literature even in reference to human Src) [39, 40] and hu- 670 This will install all dependencies except for Modeller and Rosetta, which are not available through the conda package manager, and thus must be installed separately by the user. The latest source can be downloaded from the GitHub repository, which also contains up-to-date instructions for 675 building and installing the code. [JDC: Where does docu-676 mentation reside? And example inputs for generating the results in this paper?]

Future Directions

[JDC: In the Discussion, let's be sure to talk about the limfamily [38, 45, 46]. As such, we have projected the Ensem- 600 itations and what could be improved or added in the future. bler models for Src and Abli onto a space consisting of the 681 For example, we don't yet handle counterions (e.g. strucdistances between these two residue pairs (Fig. 8). The mod- 682 tural Zn²⁺), prosthetic groups (e.g. heme), or cofactors els show strong coverage of regions in which either of the 683 (e.g. ATP) yet. We don't handle post-translational modificaelectrostatic interactions is formed, as well as a wide range 684 tions either (such as phosphorylation, methylation, glycosyof regions inbetween. We thus expect that such a set of mode lation, etc.). It's a good idea to suggest that this is an imporels, if used as starting configurations for highly parallel MD 686 tant first step toward enabling superfamily- and genomics-

Comparative protein modeling and MD simulation set-up

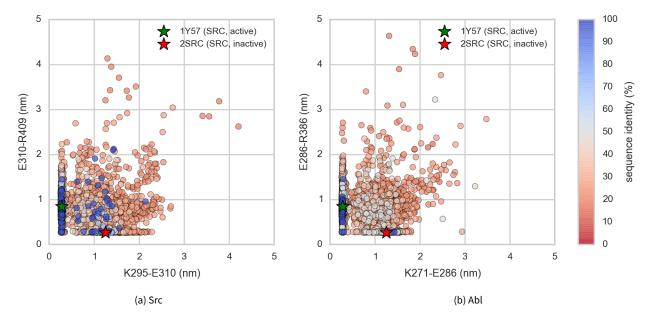

FIG. 8. Src and Abl1 models projected onto the distances between two conserved residue pairs, colored by sequence identity. Two Src structures (PDB entries 1Y57 [40] and 2SRC [39]) are projected onto the plots for reference, representing active and inactive states respectively. These structures and the residue pairs analyzed here are depicted in Fig. 7. Distances are measured between the center of masses of the three terminal sidechain heavy atoms of each residue. The atom names for these atoms, according to the PDB coordinate files for both reference structures, are—Lys: NZ, CD, CE (ethylamine); Glu: OE1, CD, OE2 (carboxylate); Arg: NH1, CZ, NH2 (part of guanidine).

ing degrees of complexity, and there are a number of obvious additions and improvements which we plan to implement in future versions of Ensembler.

693

Some amino acids can exist in different protonation states, depending on pH and on their local environment. These protonation states can have important effects on biological processes. For example, long timescale MD simulations have suggested that the conformation of the DFG motif of the TK Abl1-believed to be an important regulatory mechanism [CITE: Abl1 DFG flip evidence]—is controlled by protonation of the aspartate [47]. Currently, protonation states are assigned simply based on pH (a user-controllable parameter). At neutral pH, histidines have two protonation states which are approximately equally likely, and in this sitation the selection is therefore made based on which state results in a better hydrogen bond. It would be highly desirable to instead use a method which assigns amino acid protonation states based on a rigorous assessment of the local environment. We thus plan to implement an interface and command-line function for assigning protonation states with MCCE2 [48-50], which uses electrostatics calculations combined with Monte Carlo sampling of side chain conformers to calculate pKa values. [JDC: I think we may want to consider doing that at this stage. Let's discuss.]

non-protein atoms and molecules for proper function, such 745 the set of all human protein kinase domains listed in UniProt as metal ions (e.g. Mg⁺²), cofactors (e.g. ATP) or post- 746 have a median length of 265 residues and a standard detranslational modifications (e.g. phosphorylation, methyla- 147 viation of 45, yet the minimum and maximum lengths are 718 tion, glycosylation, etc.), and we thus plan for **Ensembler** 748 102 and 801 respectively. The latter value corresponds to

689 can be approached in a number of different ways, with vary- 719 to eventually have the capability to include such entities ₇₂₀ in the generated models. Binding sites for metal ions are frequently found in proteins, often playing a role in cataly-₇₂₂ sis. For example, protein kinase domains contain two binding sites for divalent metal cations, and display significantly increased activity in the presence of Mg^{2+} [51], the divalent cation with highest concentration in mammalian cells. Metal ions are often not resolved in experimental structures of proteins, but by taking into account the full range of available structural data, it should be possible in many cases to include metal ions based on the structures of homolo-730 gous proteins. We are careful to point out, however, that metal ion parameters in classical MD force fields have signif-₇₃₂ icant limitations, particularly in their interactions with pro-733 teins [52]. Cofactors and post-translational modifications ₇₃₄ are also often not fully resolved in experimental structures, and endogenous cofactors are frequently substituted with 736 other molecules to facilitate experimental structural analysis. Again, Ensembler could exploit structural data from a set of homologous proteins to model in these molecules, 739 although there will be likely be a number of challenges to overcome in the design and implementation of such func-741 tionality.

Another limitation with the present version of **Ensembler** involves the treatment of members of a protein family with Many proteins require the presence of various types of 744 especially long residue insertions or deletions. For example, the protein kinase domain of serine/threonine-kinase *great-* 765 wall, which includes a long insertion between the two main lobes of the catalytic domain. In principle, such insertions could be excluded from the generated models, though a number of questions would arise as to how best to approach 754
